ABSTRACT: A list of spider species recorded from the Parque Estadual Mata São Francisco, Paraná, Brazil was compiled based on 7,942 specimens, of which 2,872 are adults (36.15%) and 5,071 are juveniles (63.85%). Adults were identified as belonging to 45 families, 140 genera and 209 species and morphospecies (101 nominal species and 108 morphotypes). Forty-one species were recorded for the first time from the state of Paraná, most of them belonging to Araneidae (14), Oonopidae (4), Theridiidae (4), and Uloboridae (3). *Conifaber guarani* Grismado, 2004 and *Oonops nigromaculatus* Mello-Leitão, 1944 were recorded for the first time from Brazil. These results place Paraná as the sixth state with the highest number of records of spiders from Brazil, currently 465 species. This study increases in 10% the number of species recorded from Paraná, and the Atlantic Forest fragment becomes one of the most well sampled areas in the state, with 20% of all known species in Paraná.

INTRODUCTION

Spiders represent the second largest order within the arachnids. They are a group of predators that occur in various physical and biological conditions of the terrestrial environment (Foelix 1996). Due to this adaptive success, these animals are found in all zoogeographical regions of the world except the Arctic and Antarctic regions (Foelix 1996). With fossil records dating from the middle of the Devonian (approximately 380 million years ago), the order Araneae was one of the first groups to conquer the terrestrial environment (Selden *et al.* 1991). Currently, there are 45,081 described species of spiders, distributed in 3,928 genera and 114 families (World Spider Catalog 2014). The Neotropical region is known for its high araneofauna diversity, but is still poorly studied. Brazil has the highest diversity of spiders in the southeast region, including records of 3,203 species in 659 genera and 72 families, as reported by Brescovit *et al.* (2011).

Studies of the araneofauna from the state of Paraná, date offield expeditions conducted by European naturalists from the XIX century, who described the first species of spiders (Keyserling 1880; Simon 1893). After that, only sporadic studies were published. Mello-Leitão (1941) proposed the first spider catalog for the state, including 222 species, and a few years later (Mello-Leitão 1947) described 48 additional species. Pinto-da-Rocha (1995) recorded 11 cave dwelling species. Few non-standardized inventories were also conducted in different areas of the state (Lopes *et al.* 2006, 2008; Buschini *et al.* 2010a, b). Brescovit *et al.* (2011) published a list of 424 literature records of species recorded from the state, ranking Paraná as the sixth state in species richness of spiders from Brazil. Although the state of Paraná is only a political denomination, with no biogeographical implication, it is here used to enable the

comparisons with the previous literature (Brescovit *et al.* 2011; Mello-Leitão 1941, 1947).

In this study, we compiled a list of species from the Parque Estadual Mata São Francisco, one of the largest fragments of Atlantic Forest in northern Paraná (Bornstein and Reinert 2000), contributing towards the knowledge on the spider fauna of Brazil and highlighting the importance of the conservation of the area.

MATERIALS AND METHODS

Study site

The Parque Estadual Mata São Francisco (PEMSF) is located in the municipalities of Santa Mariana and Cornélio Procópio ($28^{\circ}08'47.3''$ S, $50^{\circ}34'19.5''$ W, 543 m average altitude), in the state of Paraná (Figure 1). It has a total area of 832.5 ha, of which 27% in the municipality of Santa Mariana and 73% in Cornélio Procópio. Agricultural properties, dominated by monocultures of soybeans, corn, wheat, and pastures surround the park (Tomé *et al.* 1999). The botanical fauna of the PEMSF includes 85 tree species (belonging to 36 families), the most dominant being: *Gallesia integrifolia* (Spreng.) Harms (Phytolaccaceae), *Croton floribundus* Spreng. (Euphorbiaceae), *Piptadenia gonoacantha* (Mart.) J.F. Macbr (Mimosaceae), *Sebastiana brasiliensis* Spreng. (Euphorbiaceae), *Pachystroma longifolium* (Ness) I.M. Johnst (Euphorbiaceae), *Nectandra megapotamica* (Spreng.) Mez (Lauraceae), *Aspidosperma polyneuron* Müll.Arg (Apocynaceae), *Alchornea glandulosa* Poepp. & Endl. (Euphorbiaceae), *Sorcea bonplandii* (Baill.) W.C. Burger, Lanjouw & Boer (Moraceae) and *Bougainvillea glabra* Choisy (Nyctaginaceae) (Tomé *et al.* 1999).

According to Maack (1950), the PEMSF is characterized by a warm, humid subtropical weather, with drier periods during winter, temperatures above 22°C during the

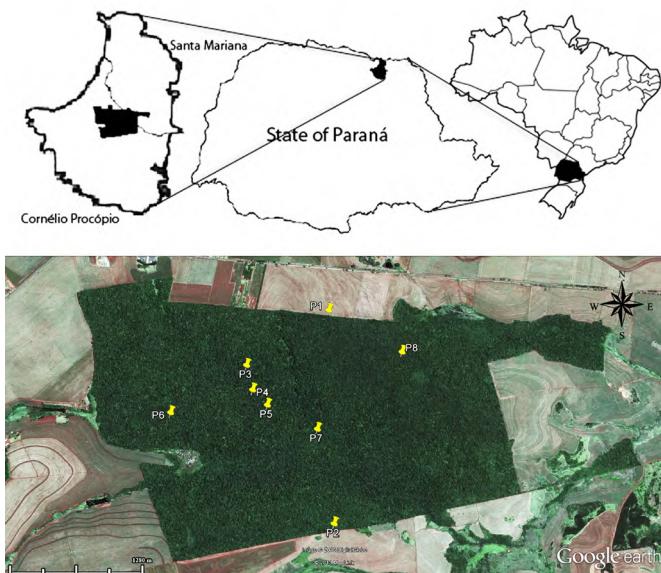

FIGURE 1. Geographic location of the eight sampling sites of the Parque Estadual Mata São Francisco, in the state of Paraná, Brazil.

warmest months and rare frosts. The average rainfall is 1200–1400 mm per year, with the trimester of December, January and February being the wettest, with an average of 500–600 mm, and the trimester of June, July and August the driest, with an average of 150–175 mm (IAPAR 2013).

Data collection

The sampling in PEMSF was conducted in eight sampling points (P1–P8, Figure 1), which were chosen due to their easy access and phytophysiological differences. We collected spiders using five sampling methods to access the fauna in different microhabitats. Nevertheless, not all methods were used in all sampling sites, as described below.

In five sampling sites, we installed 16 m² plots (P1: 23°09'03" S, 50°33'51" W; P2: 23°10'11" S, 50°33'51" W; P3: 23°09'20" S, 50°34'20" W; P4: 23°09'28" S, 50°34'18" W; and P5: 23°09'33" S, 50°34'13" W). In these, we employed four sampling methods: diurnal active manual-searching (DM), beating tray (BT), litter sifting (LS) and pitfall traps (PT). DM consisted in sampling spiders from leaflitter, fallen trunks, under rocks, bushes and tree trunks. One DM sample corresponds to 1 hour of continuous sampling (Coddington *et al.* 1991). BT was used to collect spiders that occupy shrubby stratum up to 2 m high, by beating the bushes onto a structure formed by a white cloth (60 × 60 cm), sustained by two wooden rods (80 × 2 × 2 cm) (Coddington *et al.* 1991; Podgaiski *et al.* 2007; Carvalho and Avelino 2010). One BT sample corresponds to 40 minutes of continuous sampling. LS was conducted according to Barreiros *et al.* (2005); the sampling unit for this method corresponds to the inspection of approximately 1 m² of soil, collected randomly, and sieved using a screen of 0.5 cm in the laboratory. We obtained 60 samples, 12 per sampling point, for each method described above. We used PTs, similar to those employed by Carvalho and Avelino (2010), to sample the litter inhabiting species. To prevent the excess of organic matter and rainwater inside the traps, we installed plastic plates, supported by four wooden rods, five inches above the cup openings (Indicatti *et al.* 2005). In each sampling site, we installed two pitfall

traps that we left exposed for 30 days. Each pitfall trap corresponded to one sample, totaling 120 samples, 24 per sampling point.

We delimited plots of 300 m² (30 × 10 m) in three sampling sites (P6: 23°09'35" S, 50°34'46" W; P7: 23°09'41" S, 50°33'56" W; and P8: 23°09'18" S, 50°33'26" W) (Figure 1), where we conducted nocturnal manual-searching (NM). The technique consisted in sampling spiders from leaf litter, fallen trunks, under rocks, bushes and tree trunks during 1 hour. With this sampling method, we obtained 90 samples, 30 for each sampling site.

We sampled the sites monthly for one year, from May 2009 to April 2010, resulting in 300 samples from five points (P1–P5) and 90 samples from three points (P6–P8), totaling 390 samples. We preserved all collected material in 70% alcohol and identified it with the number of the sample and area. We deposited vouchers in the collection of Instituto Butantan (IBSP 150237-150300) in São Paulo, SP, Brazil. The research in the Parque Estadual Mata São Francisco was authorized by the Instituto Ambiental do Paraná (IAP) with collecting permits from the SisBio system of the Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis (IBAMA number: 2122-1; Request: 10254).

The previous records of species we present in this study were based on Brescovit *et al.* (2011), inventories carried out in Paraná (Keyserling 1880; Simon 1893; Mello-Leitão 1947, 1941; Pinto-da-Rocha 1995; Lopes *et al.* 2006, 2008; Buschini *et al.* 2010a, b) and in the database of the collection of the Instituto Butantan — IB, Brasil.

RESULTS

We collected 7,942 spider specimens, of which 2,872 adults (36.15%) divided in 1,129 males and 1,743 females. The observed richness was 45 families, 140 genera (based only on identified genera) and 209 morphospecies with approximately 48% of these taxa identified to species level, 101 nominal species and 108 morphospecies (Table 1). Clubionidae, Oecobiidae, Philodromidae and Segestriidae were represented only by juvenile specimens. The families with the largest number of species were Theridiidae (35), Araneidae (31), Salticidae (17) and Uloboridae (10), while nineteen families were represented by a single species (Table 1 and Figure 2).

Based on the data presented by Brescovit *et al.* (2011) we found 41 new records for the state of Paraná, with major contributions from Araneidae, with 14 species (Figure 3), followed by Theridiidae and Oonopidae with four, Uloboridae with three, Linyphiidae, Pholcidae and Thomisidae with two and ten families with one species each (Table 1 and Figure 4). *Conifaber guarani* Grismado, 2004 (Uloboridae, Figure 4J) and *Neotrops nigromaculatus* (Mello-Leitão, 1944) were restricted to Paraguay, Uruguay and Argentina, and are here recorded for the first time in Brazil.

Among the sampling methods, we obtained the largest number of species using NM, resulting in 104 morphospecies (61 exclusive for this method), of which 23 were new records. BT obtained 85 morphospecies (40 exclusives), followed by PT with 65 (19), LS with 40 (4) and DM with 22 (2) species (see Table 1). Eighty-three morphospecies were sampled using two or more methods.

TABLE 1. List of species and abundance, by collection method, of the spiders obtained from Parque Estadual Mata São Francisco, Cornélio Procópio, Paraná. Information: Litter sifting (LS); Diurnal manual-searching (DM); Nocturnal manual-searching (NM); Beating tray (BT); Pitfall traps (PT); and the new records for the state.

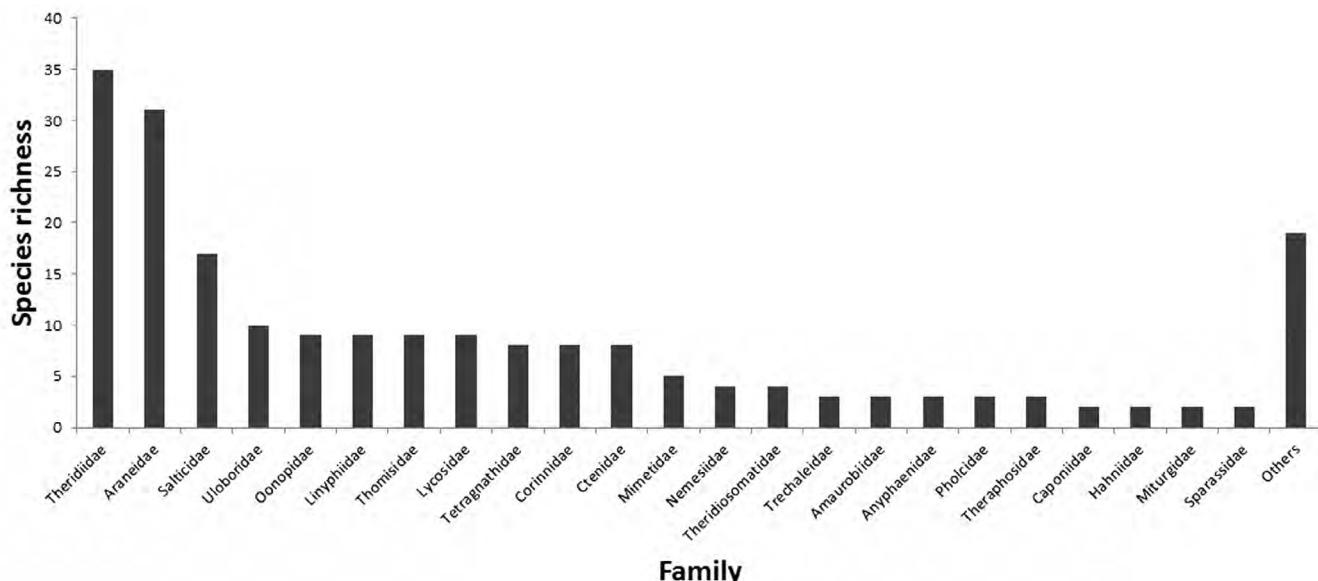

FIGURE 2. Species richness of spiders sampled from each family in Parque Estadual Mata São Francisco – PR.

DISCUSSION

Brazilian regions with the highest spider diversity are the south and southeast (Brescovit *et al.* 2011), with the most well sampled sites located in São Paulo and Rio Grande do Sul. Paraná is the sixth site in terms of number of spider records (Brescovit *et al.* 2011). However, it is important to highlight that these data are strongly biased by the large concentration of arachnologists and biological collections in these regions (Brescovit *et al.* 2011) and the low current proportion of forest in each state, which result in proportionally more complete inventories. As discussed by Brescovit *et al.* (2011) the number of species recorded from Brazilian regions is mainly explained by differences in the sampling effort; since the northern region is expected to harbor a higher diversity than the others.

The new records, as well as the large number of taxa obtained in this study is due to the use of different collecting methods, since inventories carried out in Paraná using a single method registered no more than 80 species/morphospecies (*e.g.*, Lopes *et al.* 2006, 2008; Buschini *et al.* 2010 a, b). The NM method contributed with 29,2% of the total number of exclusively recorded species, followed by BT. The number of species here obtained (209) was one of the largest recorded for the Atlantic Forest (see Azevedo *et al.* 2014). Podgaiski *et al.* (2007) used five methods and obtained 447 species/morphotypes, followed by other studies resulting in numbers between 212-293 species (Bonaldo *et al.* 2007; Álvares *et al.* 2004; Azevedo *et al.* 2014). In these studies, and ours, approximately 50% of the species were identified to species level. The taxonomic resolution in this paper and other papers dealing with spiders is relatively low if compared to others arachnids (*e.g.*, Tourinho *et al.* 2014). This fact is mainly due to the lack of taxonomic revisions and the large number of non-described species sampled from different groups (*e.g.*, Nogueira *et al.* 2006; Podgaiski *et al.* 2007; Carvalho and Avelino 2010).

Based on the literature (see Levi 1967, 1985, 1988, 1991, 1993), many species include records that are

quite distant from one another. Examples are the gaps in the geographical distribution of *Alpaida leucogramma* (White, 1841) (Figure 3B), *Micrathena plana* (C. L. Koch, 1836) (Figure 3F), *Ocrepeira covillei* Levi, 1993 (Figure 3H), *Wagneriana taim* Levi, 1991 (Figure 3J), *Chrysso pulcherrima* (Mello-Leitão, 1917) and *Platnickina mneon* (Bösenberg & Strand, 1906) (Figure 4H). *Gelanor altithorax* Keyserling, 1893 is broadly distributed in almost all of the Atlantic forest, but had not yet been recorded the sites of Paraná. *Escaphiella morro* Platnick & Dupérré, 2009 (Figure 4E), also recorded in this study, was known only from the type locality (São Paulo) and Mato Grosso, Brazil. *Triaeris stenaspis* Simon, 1891 (Figure 4F) is a parthenogenetic species with Pantropical distribution, introduced in Europe and now found in southern Brazil (see Platnick *et al.* 2012).

The large number of morphotypes and new records of Araneidae and Theridiidae are probably the result of the high richness of known species of these families in the world (World Spider Catalog 2014), since similar results were observed in several inventories conducted in Atlantic Forest fragments (*e.g.*, Silva 2005; Dias *et al.* 2006; Podgaiski *et al.* 2007). Thus, with the new records presented in this study, Paraná becomes the sixth state in Brazil with the highest number of recorded species of spiders, totaling 465 species (Brescovit *et al.* 2011). This represents an increase of 10% in the number of recorded species, and this fragment of Atlantic Forest becomes one of the most well studied areas in the state, harboring one of the largest inventories carried out in Paraná, with a record of 20% of all known species.

ACKNOWLEDGEMENTS: We are grateful to Jefferson Oliveira, for helping during fieldwork, J. Ricetti and J. Zequi for initial orientation and sampling design of this work. We thank Cristina A. Rheims for reviewing the English language, Sylvia M. Lucas, R. P. Indicatti, Y. Lemos, A. M. Giroti, P. Goldoni, L. F. Moura, B. A. Huber, G. S. Ruiz, D. F. Candiani, A. J. Santos and S. C. Dias for helping in the identification and provision of literature. We are grateful to A. Sánchez, A. A. Nogueira and J. Cabra who reviewed and helped to improve the draft of this manuscript. We are also grateful for Regiane Saturnino, Ana L. Tourinho and Nancy Lo-Man-Hung for review and comments on the manuscript. The authors were supported by CNPq (301776/2004-0 - ADB) and FAPESP (2012/04157-9 - ADB).
