Abstract: We present a new distribution map, including new locality records for the Blue-fronted Lancebill (*Doryfera johannae*) from southeast Peru. One of these records is the first physical capture record for the Madre de Dios region and supposes a range extension of ca. 470 km to the southeast. We provide notes related to the environment in which this individual was found, along with photos of the captured female from the Manu Learning Centre in the buffer zone of Manu Biosphere Reserve.

Key words: *Doryfera*, hummingbird, distribution, range extension, trochilidae

The Blue-fronted Lancebill (*Doryfera johannae)* is a hummingbird found in Brazil, Colombia, Ecuador, Guyana, Peru, and Venezuela (Avibase 2013; Stotz et al. 1996; Schuchmann 1999). Its natural habitats comprise subtropical or tropical moist lowland forests and subtropical or tropical moist montane forests, mostly along the eastern slopes of the Andes (IUCN 2013). Two subspecies are currently recognised: *D. johannae johannae* (east slope of Andes from central-eastern Colombia to central Peru) and *D. johannae guianensis* (southern Guyana, southern Venezuela and *tepuis* of adjacent northern Brazil) (Avibase 2013; Figure 1). Schulenberg et al. (2007) report its elevational range as between 500–1,400 m above sea level (a.s.l.) and its abundance in Peru as uncommon.

Within Peru, maps of distribution currently show its existence only in northern and central Peru (BirdLife International and NatureServe 2012; InfoNatura 2007; IUCN 2013; Schulenberg et al. 2007; Clements and Shany 2001), with the exception of a visual sighting and audio recording at Amazonia Lodge (071°22′32.934″ W, 012°52′12.0138″ S; 500–1050 m a.s.l.) in southeastrn Peru (Walter et al. 2006; Xeno canto 2013).

Based on a model of Amazonian deforestation, over three generations (12 years) the Blue-fronted Lancebill is expected to lose 16.2–17% of suitable habitat within its distribution (Soares-Filho et al. 2006). Based on these figures the species is predicted to decline by <25% during this time (IUCN 2013), therefore understanding more about its basic ecology and present distribution is critical for future potential conservation efforts.

The locality Mascoitania holds a research station and lodge; the Manu Learning Centre (071°23′28.06″ W, 012°47′21.849″ S, 460 m a.s.l.). The lodge is situated next to the Alto Madre de Dios River in the buffer area of Manu National Biosphere Reserve, on the eastern Andean foothills; between Manu National Park and the Amarakaeri Communal Reserve (Figure 1). Mascoitania is a 643 ha private reserve owned by The Crees Foundation, hosting tourism, research and volunteering activities. It contains areas of primary terra firme, regenerating logged, regenerating clear-felled and bamboo forest with an altitudinal gradient of approximately 460–700 m a.s.l. Over 485 species of birds have been recorded to date at the Manu Learning Centre, including 28 species from the family Trochilidae (species list available from research@crees-manu.org). All mist netting at the Manu Learning Centre was conducted under permit provided by the Ministry of Agriculture of Peru; Permit Number: 25397; Authorisation Number (Autorización No.) 2904-2012-AG-DGFFS-DGEFFS.

A map was created using presence locations of *D. johannae* as recorded in the literature (Appendix 1). Environmental factors were taken from WorldClim (version 1.4; http://www.worldclim.org; Hijmans et al. 2005) and added to the modelling program MaxEnt (version 3.3.3e; http://www.cs.princeton.edu/~schapire/maxent/; Phillips et al. 2004, 2006). No land use variables were included due to the historical nature

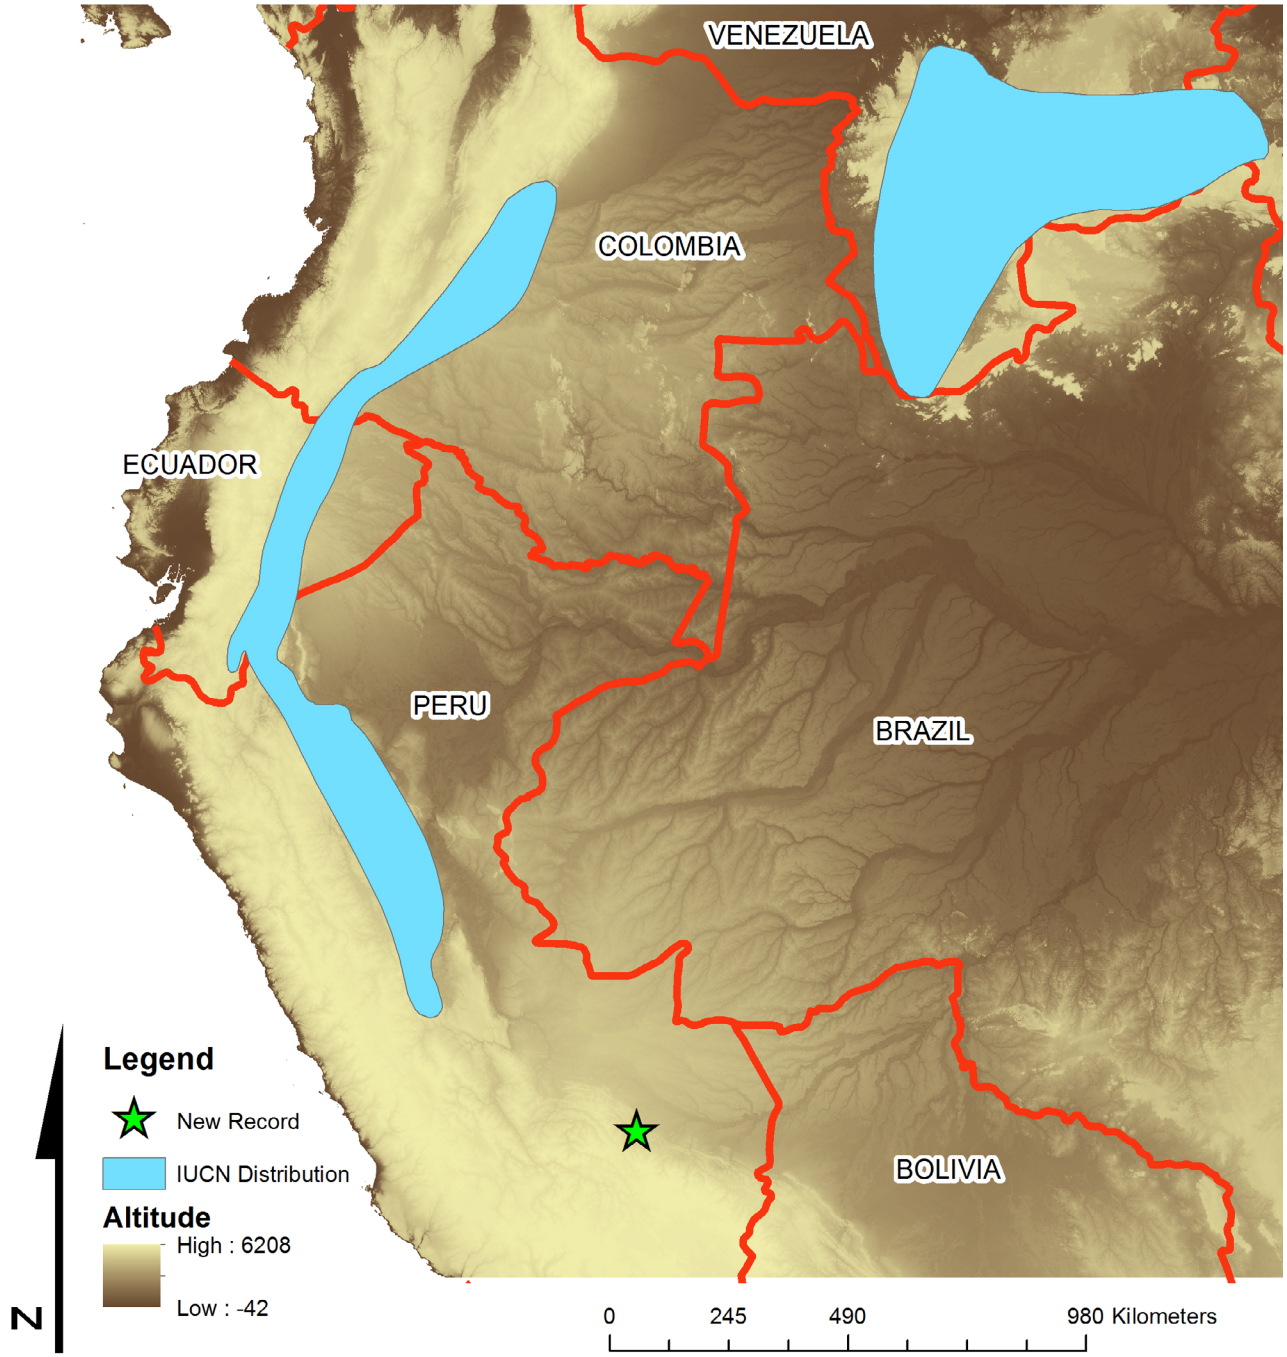

Figure 1. Map of the known distribution of *D. johannae* shaded in blue and the new locality record for *D. johannae johannae* in Peru, ca. 470 km to the southeast (shown by green star). Distribution shapefile taken from BirdLife International and NatureServe (2012).

of the presence locations. MaxEnt has been shown to perform well at low sample sizes (Hernandez et al. 2006, Raxworthy et al. 2007), such as the sample size for *D. johannae*. Five pilot models were constructed using the WorldClim data, four of which focussed on a different environmental variable (e.g., precipitation), with the fifth including all environmental variables. Variables with the highest permutation importance to each pilot model were used to construct a further model (Baldwin and Bender 2008). This model was jackknifed to assess variable importance and to identify highly correlated variables (Baldwin 2009). The final model was bootstrapped (100 replicates) to create a continuous logistic output of probability distribution.

In order to address sampling bias all models were run with a mask to limit the area used for background points by MaxEnt (Merow et al. 2013). The mask was determined by splitting the samples into two distinct groups (sample A and sample B, Figure 3). A minimum convex hull was drawn around each sample group, buffered by the observed mean distance for each group determined by running the Average Nearest Neighbor tool in ArcGIS 10 Spatial Analyst. Results from the model were then projected onto the previously masked area

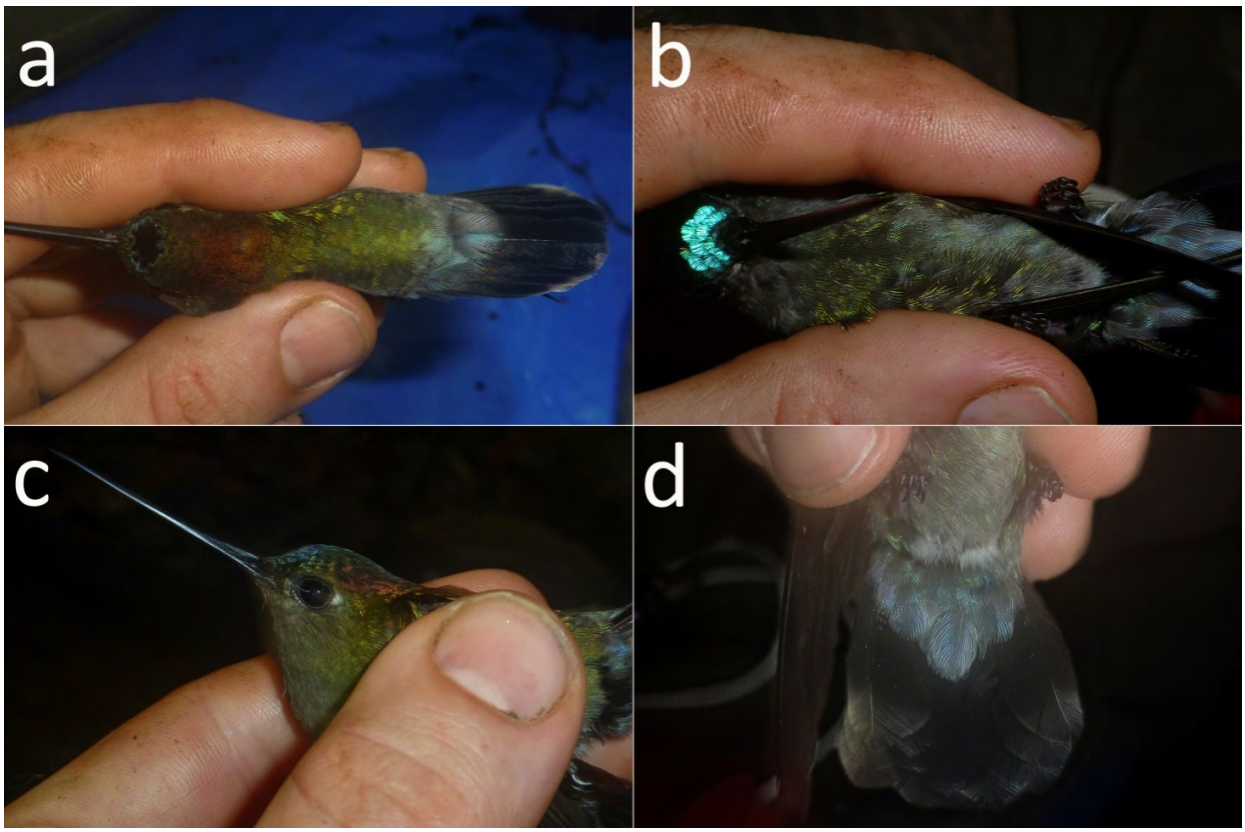

Figure 2. Photographs of the captured female individual.

using MaxEnt. To create a binary suitable/unsuitable habitat map the output was processed in ArcGIS 10 using the maximum training sensitivity plus specificity logistic threshold (Cao et al. 2013).

At 7:25 h on 2 August 2013, a female *D. johannae* was captured during a mist-netting session on the Mascoitania land (071°24′25.886″ W, 012°48′33.475″ S, 700 m a.s.l.) on the western side of the Alto Madre de Dios basin, Madre de Dios Region. It was captured in a 10 m mist-net setup heading east to west along a ridge line trail within primary forest. The bird was measured (Table 1), photographed (Figure 2) and then released.

The map in Figure 3 shows the presence locations of *D. johannae* as recorded in the literature along with the predicted distribution map created in this study. The average training area under curve (AUC) value for the replicate runs in the receiver operator characteristic (ROC) output was 0.92 in the final model, showing a very good model fit. However, there is evidence of some overprediction and it should be noted that the map shows only potential and not realised distribution (Phillips et al. 2006).

Previous maps of the distribution of *D. johannae* show the species to be present in northern and central Peru. This mist-net capture from the Mascoitania land is the first physical capture record for the Madre de Dios region and the Manu Biosphere Reserve. Along with other audio and visual records from southeast Peru our findings represent a range extension for the species from the Pasco region of central Peru to ca. 470 km to the southeast. Our map projection indicates that this species may exist even further to the southeast of Peru and into the northwest region of Bolivia. However, as there is evidence that the map may show some degree of over prediction (Phillips et al. 2006), physical verification of this predicted presence in Bolivia is needed.

ACKNOWLEDGEMENTS

We first of all thank The Crees Foundation (http://www.crees-manu.org) and its director Quinn Meyer for supporting this research as part of their conservation and biodiversity monitoring programme and also the University of Glasgow for supporting field work conducted at the Manu Learning Centre (MLC). We gratefully acknowledge the financial support and encouragement of the TJMF Foundation who provided crucial support for this work through their Amazon Research Programme grant to the University of Glasgow. Thanks to the Darwin Initiative for financial support of the Sustainable Manu project, a collaborative

Table 1. Physical measurements (in g and mm) from the captured female

Weight	Primaries	Tail length	Total length	Culmen length	Culmen width	Culmen depth
8.5 g	52 mm	29 mm	95 mm	32.5 mm	3.1 mm	2.5 mm

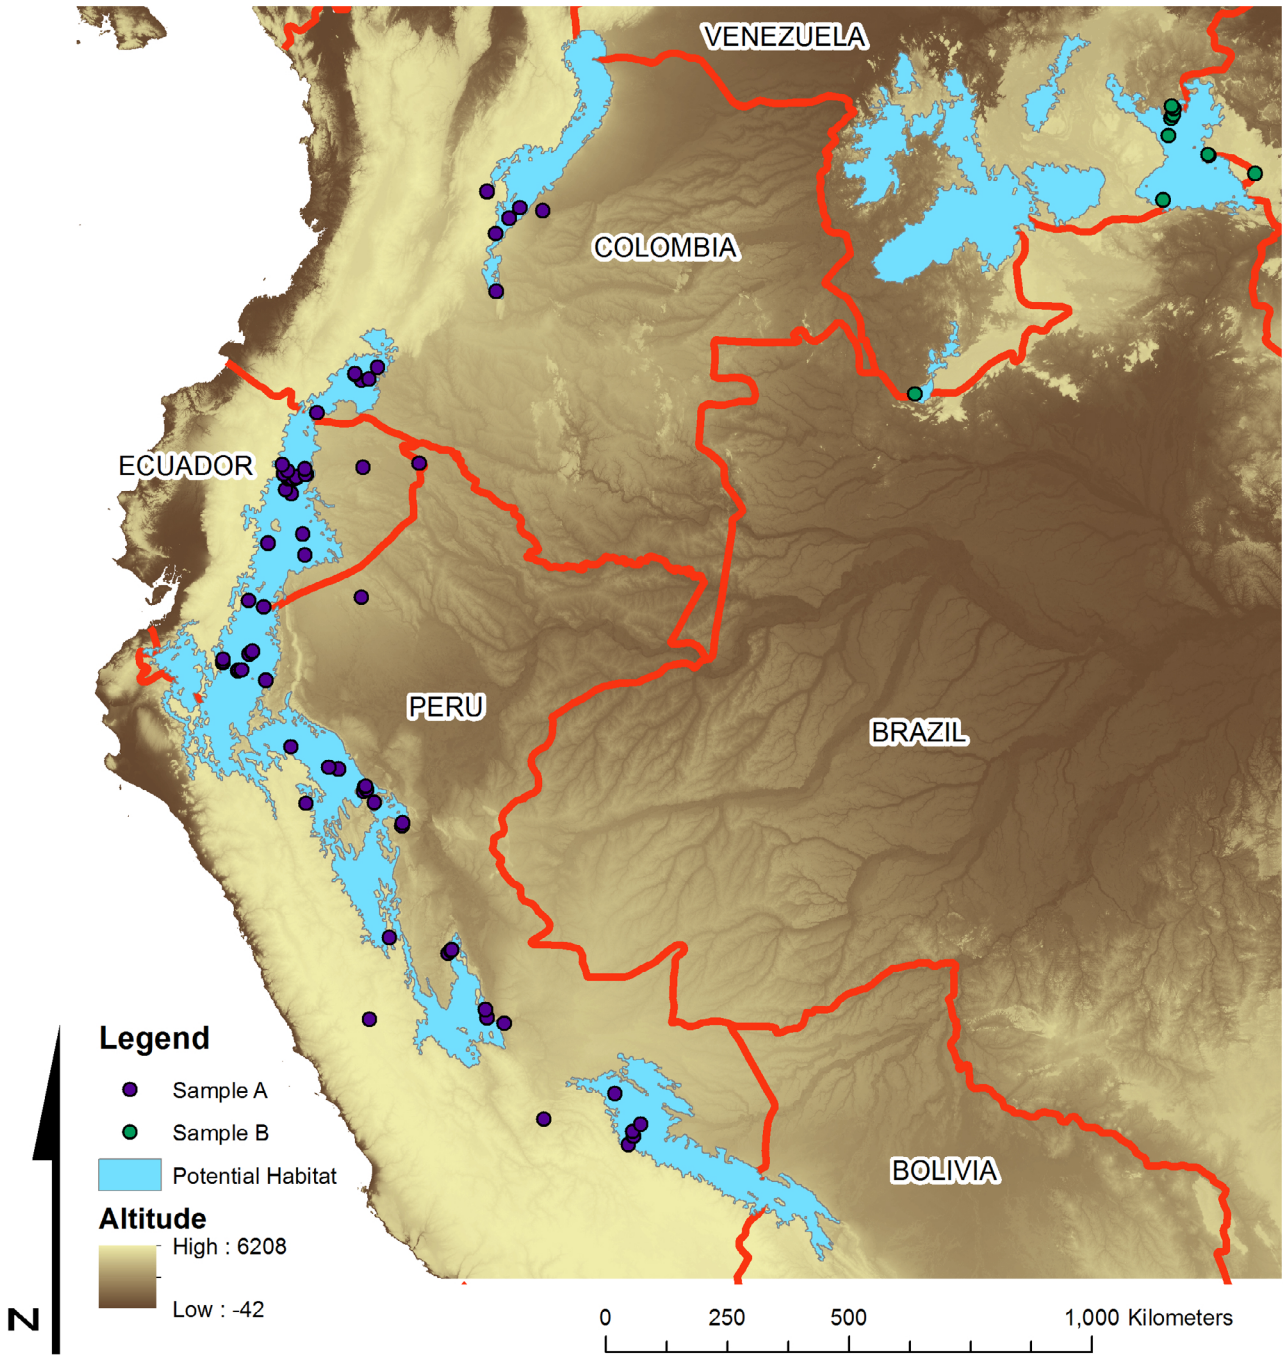

Figure 3. Known locality records of both *D. johannae johannae* (Sample A records) and *D. johannae guianensis* (Sample B records) and a map of the potential distribution; with new records from southeast Peru projecting a range extension for the species of approximately 470 km to the southeast, from the Pasco region of central Peru.

initiative between The Crees Foundation and The University of Glasgow that supported this research. Thanks to all the staff of the Manu Learning Centre and Crees for providing a comfortable and beautiful place to stay and conduct research. Specific thanks go to other mist netting staff of the Crees research team; Jasmine Rowe and Alice Risely. Thanks also to the Ministerio de Agricultura of Peru for providing the permit to conduct research in Peru.Finally, thanks to all the volunteers and visitors of Crees for supporting the research and making the work possible.
