Abstract: *Ganoderma* is a cosmopolitan genus of fungi with species distributed in temperate and tropical regions. Species of *Ganoderma* in living Leguminosae were observed in Park de la Salud in Pance, Cali, Colombia and we record *G. multiplicatum* for the first time from Colombia. A distribution map of this genus in the Neotropical region is presented.

Key words: Ganodermataceae; Leguminosae; taxonomy; Neotropics

The genus *Ganoderma* P. Karst was created by Karsten (1881) to recognize a lacquered and stipitate fungus, *Polyporus lucidus* (Curtis) Fr., the type of the genus (Moncalvo and Ryvarden 1997). *Ganoderma* is well circumscribed by its truncated, ellipsoid basidiospore with apical germinal pore and, double walls structure; the external wall (exosporium) is thin and hyaline, and the internal wall (endosporium) is dark brown and separated with internal crests (Ryvarden 2004). Due to the high phenotypic plasticity found in the basidiomata of this genus and varying concepts of the species, identifying some *Ganoderma* species is confusing and correct geographical distributions are still pending (Moncalvo and Ryvarden 1997). The genus is considered to be cosmopolitan with species distributed in temperate and tropical regions worldwide (Cao and Yuan 2013). In Colombia, *Ganoderma* has not been studied in depth, but morphology-based studies and previous work on the diversity of macrofungi in Colombia included thirteen species of *Ganoderma* (Vasco-Palacios and Franco-Molano 2013). A list of species, locality, voucher and references are presented in Table 1.

Ganoderma multiplicatum (Mont.) Pat. was originally collected in French Guyana on a tree trunk (Moncalvo and Ryvarden 1997). This species has been considered most similar to *G. chalceum* (Corner 1983). However, Ryvarden (2000) considered it a synonym of *G. subbamboinense* Henn., but a molecular phylogenetic analysis (ITS region) by Lima et al. (2014) showed that *G. chalceum* and *G. subbamboinense* are in different clades, suggesting they are not synonymous. During a search for species of *Ganoderma* in living Leguminosae and in rotten logs in urban and rural areas, we collected a basidiome of *G. multiplicatum* at Park de la salud (03°19'42" N, 076°38'19" W), Cali, Colombia (Table 1). The collection was made according to the methodology of Fidalgo and Bononi (1984). To analyze morphological characters, thin sections of basidiome were prepared and treated with 4% KOH, 1% Phloxine, and Melzer reagent (Ryvarden 2004). Vouchers were deposited at the herbarium of the Botanical Institute of São Paulo (SP) and the herbarium at the Valley University in Colombia (CUVC). DNA analysis (isolation, amplification and sequencing) for ITS region was performed according to protocols used by Raeder and Broda (1985), Moncalvo et al. (1995), Gottlieb et al. (2000). Primers set BMB-CR (5'-GTACACACCGCCCCGTCG-3') and LRI (5'-GGTTGGTTCTTTCTT-3') were used under conditions described by Vilgalys and Hester (1990). Sequences were aligned using BioEdit 7.2.0 (Hall 1999). Best model of nucleotide substitution (HKY+G) was selected by the Akaike criterion in JModelTest version 2.1.3 (Darriba et al. 2012). Maximum parsimony and likelihood was performed using PAUP version 4.0b10 (Swofford 2002). Bayesian analysis was performed using MrBayes 3.04b (Ronquist and Huelsenbeck 2003).

Ganoderma multiplicatum (Mont.) Pat., Bull. Soc.

Micol. Fr. 5: 74, 1889.

≡ *Polyporus multiplicatus* Mont., Ann. Sci. Nat. Bot. Ser. 4, 1: 128, 1854.

Figures 1–9.

This species presents basidiomata 14 × 10 × 3 cm, dimidiate to sessile perennial, margin whitish, lobulate, shiny laccate surface, pale light brown to reddish brown, pores angular to round, 4–6 per mm, pore surface creamy to ochraceous; cuticle formed by clavate hyphal ends, strongly amyloid in the apical part, with a few protuberances and basidiospores 8.4 × 5.8 µm.

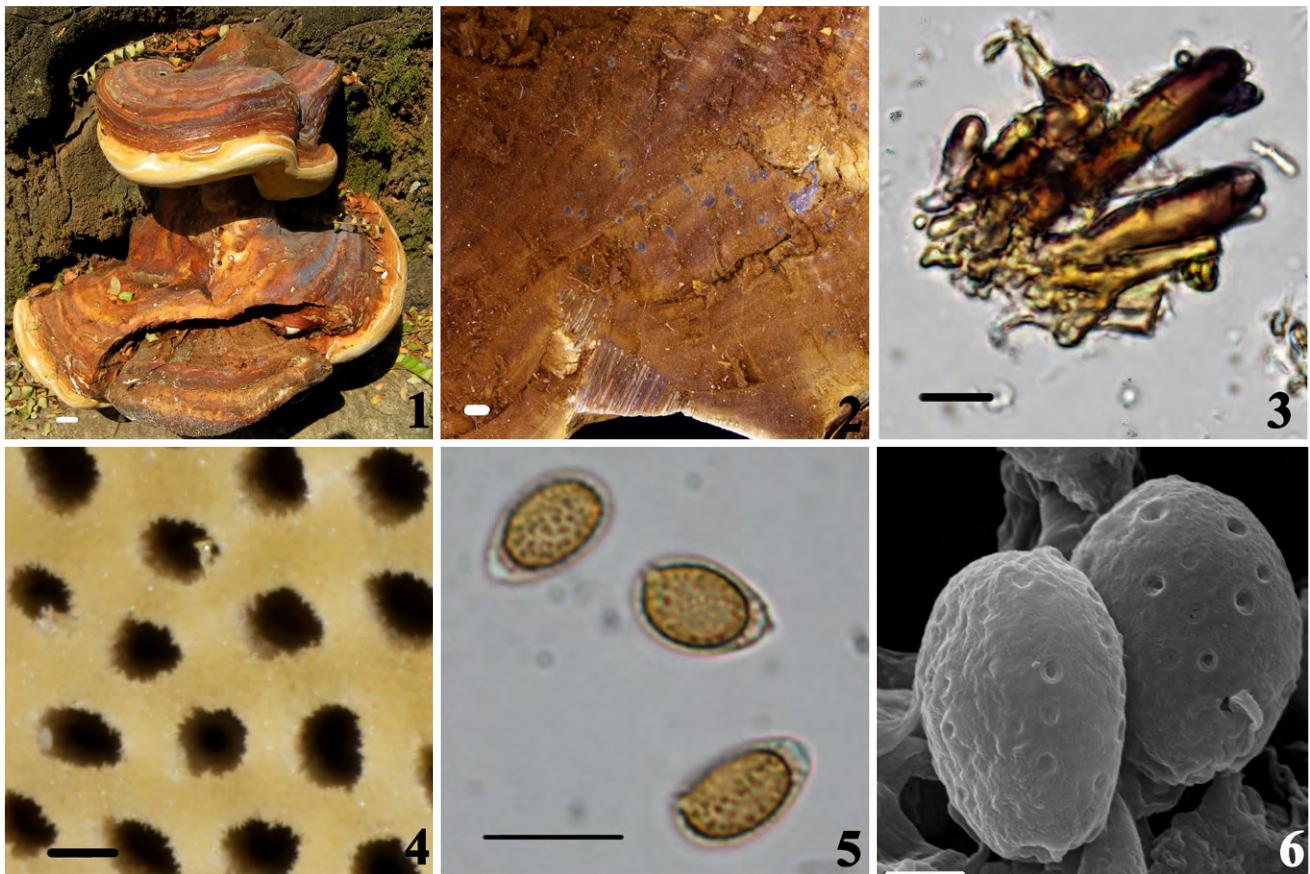

Specimen examined: Colombia: Cali, Dept. Valle, Park de la Salud, Pance, 05.I.2013. A.C. Bolaños and G. Aguiar (CUVC60077).

Additional specimens examined: Brazil. São Paulo, SP417797, SP417778, SP417780; French Guyana K123639 lectotype.

In the Neotropical region, *Ganoderma multiplicatum* was cited in Venezuela (Ryvarden 2004) and in Brazil it has been mentioned from Alagoas (Torres-Torres et al. 2012), Amazonas, Para and Rondônia (Gomes-Silva and

Gibertoni 2009; Torres-Torres et al. 2012), Mato Grosso do Sul (Quevedo et al. 2012), Paraíba (Lima et al. 2014), Rio de Janeiro (Torres-Torres et al. 2012), Roraima (Gomes-Silva et al. 2011), São Paulo (Gugliotta et al. 2011; Torres-Torres et al. 2012), Santa Catarina (Loguerico-Leite et al. 2005; Drechsler-Santos et al. 2008; Baltazar and Gibertoni 2009), and Sergipe (Torres-Torres et al. 2012). In Argentina, this species has been reported from Tucumán, Corrientes and Chaco (Gottlieb and Wright 1999). A list of localities, substrates and vouchers can be found in Table 2.

This is the first record of the species from Colombia and contributes to the list of *Ganoderma* species from Colombia and the Neotropics. The type material of *G. multiplicatum*, from French Guyana, is in Kew herbarium (K), and it consists of a basidiome fragment. Nevertheless, it allowed for the identification of our Colombian specimen. Although originally described from South America, *G. multiplicatum* was subsequently found in Africa and Asia (Steyaert 1980; Zhao 1989), including India (Bhosle et al. 2010) and Taiwan (Wang

Figure 10. Geographical distribution map of *Ganoderma multiplicatum* from Colombia and South America. (Source map: Robledo et al. 2016).

and Wu 2007). The distribution of *G. multiplicatum* in the Neotropics is shown in Figure 10.

In our phylogenetic analysis, the Colombian sample was found to be *G. multiplicatum*, with high statistical support (Bootstrap: MP: 80%, ML: 82%, BPP: 0.9), using the ITS region and including 26 additional sequences from GenBank. According to Lima et al. (2014), and in this analysis, *G. chalceum* and *G. subbamboinense* were recovered in different clades (Figure 11).

ACKNOWLEDGEMENTS

We thank SP and CUVIC herbaria for facilitating the equipment used in this study. We also thank the Support Foundation for Scientific Research of the State of São Paulo (FAPESP) and the Universidad del Valle in Colombia for financial support, Alex Mora for his help with the molecular analyses in PAUP program, Viviana Motato for the illustration, and Dr. Gerardo Robledo for the map.

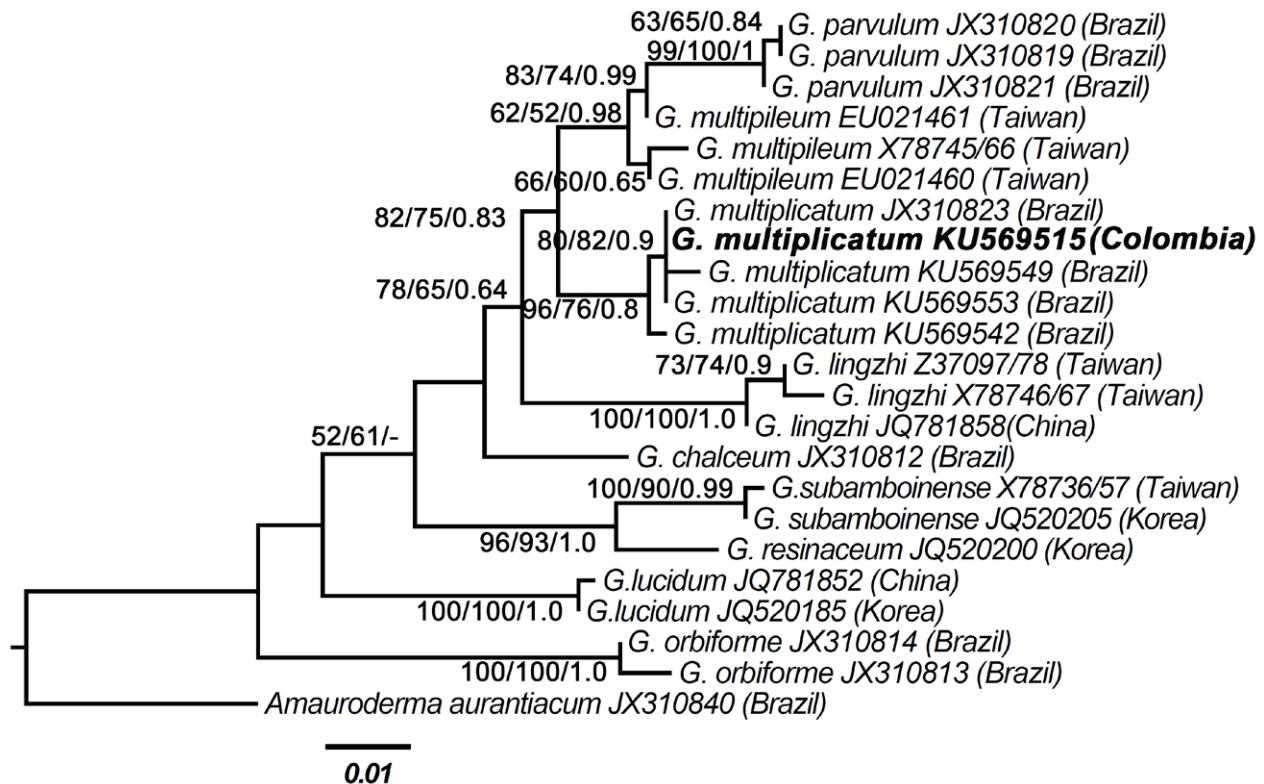

Figure 11. ITS tree and reconstruction of the phylogenetic ITS of the sequence of *G. multiplicatum*. Statistical support nodes include the maximum parsimony bootstrap, maximum likelihood and Bayesian respectively.
