Abstract

Trees and lianas were inventorized in Barail Wildlife Sanctuary, Assam, India, which revealed the occurrence of 112 and 23 species of trees and lianas respectively. Two separate lists, one for trees and other for lianas, of all the enumerated taxa are presented here with their vernacular names, phenology, places of occurrence and collection number(s). Threat status of each taxon according to IUCN Red List categories is also provided. Anthropogenic activities and other natural calamities are causing serious threats particularly to the tree diversity of the sanctuary. In addition, destruction of one tree may eradicate many lianas from a particular area. Thus, many species of trees and lianas are under alarming threat in the sanctuary. Conservation through *in situ* and *ex situ* modi operandi is recommended.

Key words

Arboreal angiosperms; Barak Valley; biodiversity; Cachar; species inventory; woody climbers.

Introduction

Inventorization of plants of a particular area comprises basic biodiversity studies and assessment of their conservation status. Among various ecoclimatic zones, tropical evergreen forests constitute one of the most biodiversity rich habitats on the globe (Khandekar and Srivastava 2014). An exhaustive inventory of tropical plant species is, thus, one of the primary objectives for the plant taxonomists. Within India, the tropical monsoon climate that prevails in the Eastern Himalayas, Northeastern India, and Western Ghats allows for a rich and diverse flora. Though steps have been taken towards cataloguing the biodiversity of protected areas in India, knowledge of the diverse flora of many protected areas, particularly in northeastern India, is still lacking. There was no comprehensive study on the diversity of angiosperms of Barail

Wildlife Sanctuary (BWS), Assam, India, and hence, we initiated this study to investigate the same of BWS for the first time. Because the angiosperm flora of BWS is large, we have segregated the study into 2 parts. A second part, which will include herbs, shrubs, and non-woody climbers, is planned for a later publication.

Tropical vegetation, mostly dominated by angiosperm trees, is a large part of floral diversity. Trees are important in that they provide shade and shelter for herbaceous and epiphytic plants. They provide homes for wild animals, especially primates. They stabilise the soil, counteract rapid run-off of rainwater, and prevent desertification, and they have a role in climate control and in the maintenance of biodiversity and ecosystem balance (Bellefontaine et al. 2002). Trees are also economically important for yielding timber, fuel, and food.

Lianas, or woody climbers, are likewise important components of tropical forests and are important for the forest community and structure. They are generally long-stemmed, reaching up into the tree canopy to get access to light. Their structural morphology and mechanisms of twining add to the complexity of the vertical structures of forests (Chaudhuri and Naithani 1985). According to Grubb (1977), dense vegetation of lianas in a particular area portray the nature of tropical lowland and lower montane forest types of that region. Like trees, lianas also contribute substantially to the diversity of the forests and provide food and arboreal pathways for forest animals. They are widely used for medicine, food, house construction, and artisan work. They have an important role in forest regeneration (Bongers et al. 2002).

The first comprehensive floral account of Assam was the *Flora of Assam* (Kanjilal et al. 1934–1940). Subsequently, Das (1942) documented preliminary data on flora of Assam. Recently, Choudhury (2005) and Barooah and Ahmed (2014) provided checklists of the vascular plants, particularly angiosperms and gymnosperms, of the state. Additionally, smaller works on the flora in various areas of the state, particularly from the Brahmaputra Valley region, include: Rao and Rabha (1966), Rao and Verma (1970, 1972, 1973, 1976), Islam (1986, 1990, 1990a, 1991), Sarma (1990), Barua (1992), Choudhury et al. (1994), Agarwal and Borah (2001), Barooah and Mahanta (2006), Sarma et al. (2006).

By comparison, the Barak Valley (southern Assam), where Barail Wildlife Sanctuary is situated, has received very little attention by botanists. Dutt et al. (1974) prepared a preliminary checklist of the Polypetalae of North Cachar Hills and Barail range (particularly the Haflong hills). Other reports from Barak Valley were made by Sharma et al. (2002), Das and Dutta Choudhury (2003), Nath and Maiti (2003), Baruah et al. (2006), Das et al. (2006, 2007, 2008), Barbhuiya et al. (2009), Darlong and Bhattacharyya (2011), Rout et al. (2012), Darlong et al. (2013), Barbhuiya 2013a, Devi and Bhattacharyya (2013, 2013a, 2013b, 2014, 2016), Barbhuiya 2014, Barbhuiya et al. (2014), and Devi et al. (2014). Das et al. (2013) and Baruah and Dutta Choudhury (2015) listed the herbaceous plants of Barak Valley, focusing on their economic utility.

Among the angiosperms of the BWS, while describing a new Asian genus of ginger, *Larsenianthus*, Kress et al. (2010) reported 2 species of the genus from the sanctuary viz. *L. assamensis* S. Dey, Mood & S. Choudhury (described as new to science from BWS) and *L. careyanus* (Benth.) W.J. Kress & Mood. Barbhuiya et al. (2012) and Barbhuiya (2013) described 2 new species, *Ornithochilus cacharensis* Barbhuiya, B.K. Dutta & Schuit. (Orchidaceae) and *Toxicodendron bimannii* Barbhuiya (Anacardiaceae), respectively. Barbhuiya et al. (2012a) rediscovered *Ardisia keenanii* C.B. Clarke (Myrsinaceae) after a gap of 138 years from the sanctuary. First collection of this species from the study area was made by R.L. Keenan in 1873. Later, C.B. Clarke (1882) described it in *Flora of British India* based on his own collection from

Manipur in 1868 and Keenan's collection from Cachar in 1873. Barbhuiya et al. (2013) documented 96 species of grasses from Barak Valley, including 16 species from the BWS.

As can be seen from the literature, it is evident that baseline data on angiosperm diversity of the BWS is mostly scattered and inadequate. Hence, we initiated this study to provide a comprehensive list of angiosperms in the sanctuary. In this first part, we treat the trees and lianas of the protected area.

Methods

Study site. Barail Wildlife Sanctuary (BWS) is situated in the northern part of Cachar district of Assam and lies along the foothills of the North Cachar and Barail hills. It covers an area of just over 326 km². The BWS is under the administrative control of the Southern Assam Forest Circle, Silchar, and consists of Barail Reserve Forest, which is part of the Cachar Forest Division (East Block) and North Cachar Reserve Forest, part of the Karimgunj Forest Division (West Block) (Fig. 1).

The climate is tropical and humid; the average annual rainfall is 3383.5 mm/year and the average humidity is 72–83%. The minimum and maximum temperatures recorded during our study were 12.6 °C and 32.7 °C, respectively.

Major rivers draining the sanctuary are the Jatinga, Daloo, Kayong, Gumra, and Boleswar. The sanctuary is characterized by undulating hills having altitudinal range of less than 30 m to more than 1800 m in the Barail hills, where the towering peaks are Hamplopet (1,867 m), Kuakaha (1,736 m), Maheo (1,739 m), and Sherpai (1,657 m) (Anonymous 2006). Geologically, the soils are sandy-stony to clayey (Anonymous 2006). The area is one of the richest treasure houses of flora as well as fauna due to its unique geographical position, diverse landscapes, wide range of physiographic conditions and high precipitation.

As per classification of Champion and Seth (1968), the sanctuary has 2 broad groups of forests, tropical wet evergreen and tropical semi-evergreen forests.

Field survey and data collection. We made extensive and intensive field observations and collections from 2013 to 2016 (Table 1), from various habitats and forest types (Figs 2, 3). Our surveys and collections were done with the permission from the Divisional Forest Officer, Cachar Division, Silchar (letter No.B/35/Misc.7344-45, dated Silchar, 21 November 2013). Although we surveyed in almost all seasons, most field surveys were done during the pre-monsoon and post-monsoon seasons. Specimens were collected mostly during their flowering and fruiting stages. Vernacular names, phenological data, and ecological notes were compiled from our field observations and a survey of the literature; these data were supplemented by collectors' notes on herbarium sheets. The IUCN Red List was used to categorize species (IUCN 2017) into different Red List categories.

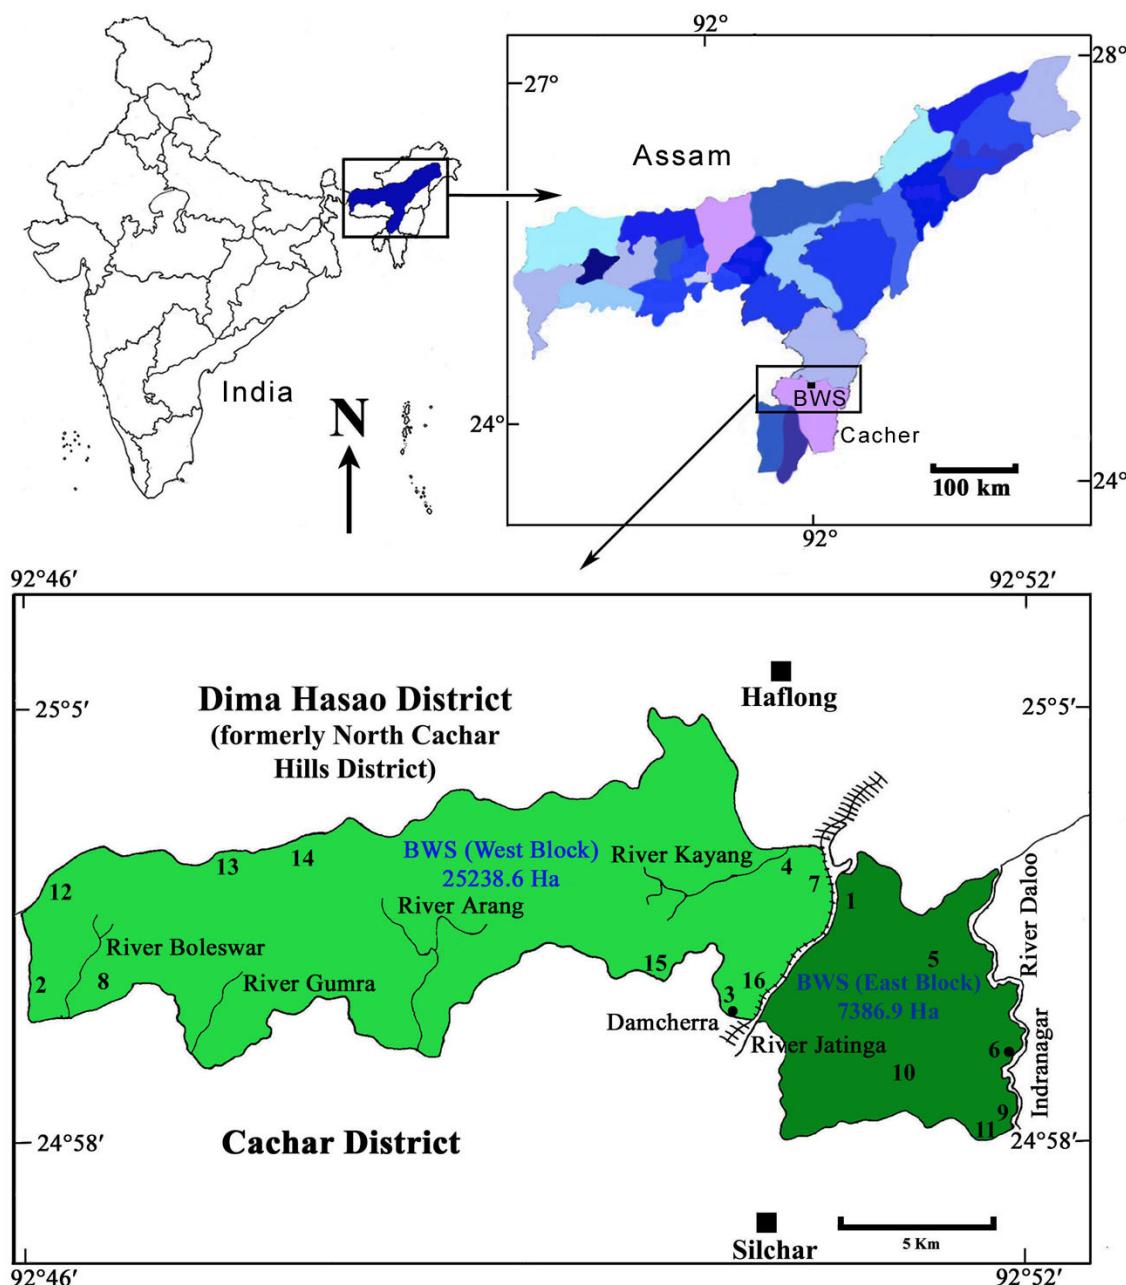

Figure 1. Map of the Barail Wildlife Sanctuary in Assam, India. See Table 1 for numbered localities.

Table 1. Localities, with dates of collections (surveys were 4–5 days at each location), elevation, and geographic coordinates. Locality number corresponds to numbers in Figure 1.

No.	Location	Date	Elevation (m)	Latitude (N)	Longitude (E)

Processing of specimens. The drying, treatment with chemicals, and mounting of our specimens were done following the routine herbarium practices (Jain and Rao 1977, Singh and Subramaniam 2008). Voucher specimens were deposited in the Plant Taxonomy and Biosystematics laboratory, Department of Life Science and Bioinformatics, Assam University, Silchar (here abbreviated as AULS; Tables 2, 3).

Identification of species. We studied the external morphological characteristics, including those of dissected, mainly floral parts, of all collected specimens using an Olympus SZ61 stereomicroscope. Characteristics of each species and infraspecific taxon were noted. Preliminary identifications were made using keys in authoratative literature (Brandis 1906, Kanjilal et al. 1934–1940, Chaudhuri and Naithani 1985). We confirmed the identifications of our specimens with authentic herbarium specimens housed in Indian herbaria (ASSAM, BSD, CAL, DD, GUBH, and LWG; acronyms according to Thiers 2011) and with images of type specimens available in online databases. The *International Plant Name Index* (IPNI 2012), *The Plant List* (2013) and *Tropicos* (2017) were consulted for current nomenclature of all taxa. The Angiosperm Phylogeny Group III Classification (APG III 2009) was followed for the classification of families. Families and species in our list are arranged in alphabetical order.

Results

Floristic diversity. Our study revealed 112 species of trees belonging to 86 genera and 43 families (Table 2), and 23 species of lianas in 17 genera and 13 families (Table 3).

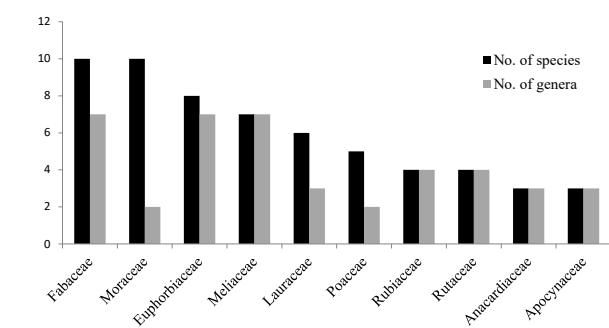

Figure 4. Dominant tree families with number of species and genera.

Of the species of trees, among the dicotyledons, the most dominant families were Fabaceae and Moraceae with 10 species each, followed by Euphorbiaceae (8), Meliaceae (7), Lauraceae (6), and Rubiaceae and Rutaceae (4 each) (Fig. 4). Seven families—Anacardiaceae, Apocynaceae, Bignoniaceae, Combretaceae, Elaeocarpaceae, Malvaceae, and Myrtaceae—each had 3 species. Actinidiaceae, Boraginaceae, Dilleniaceae, Lamiaceae, Primulaceae, Rhamnaceae, and Verbenaceae had 2 spp. each. The remaining 20 families were represented by a single species in the BWS. *Ficus* (6 spp.), followed by *Artocarpus* (4 spp.), *Bauhinia*, *Litsea*, and *Terminalia* (3 spp. each) were the dominant genera in terms of species numbers. Among the monocotyledons, only Poaceae (5 spp.) and Arecaceae (3 spp.) were recorded. Bamboos (Poaceae) and Areca nut (Arecaceae) were 2 dominant floral components in parts of the BWS.

Of the lianas, among the dicotyledons, the most dominant families were Fabaceae (8 spp.), followed by

Table 2. List of trees with their vernacular names, phenology, collection number, occurrence and threat status. Abbreviations, languages: A = Assamese, B = Bengali, Di = Dimasa, E = English, H = Hindi, K = Kuki, Sylh. = Sylheti; IUCN status: DD = Data Deficient, LC = Least Concern, NE = Not Evaluated and V = Vulnerable. Occurrence: see Table 1 for a key to locations.

Combretaceae (3 spp.) and Apocynaceae (2 spp.) (Fig. 5). The rest of the 9 families had a single species recorded. The dominant genera were *Phenera* (5 spp.) and *Combretum* (3 spp.). Among the monocotyledonous lianas, a single species (of Smilacaceae) was recorded. Photographs of several species are shown in Figs 8–11.

Common timber yielding trees recorded in the sanctuary were *Artocarpus chama* Buch.-Ham., *A. heterophyllus* Lam., *Azadirachta indica* Juss., *Gmelina arborea* Roxb. ex Sm., *Melia azedarach* L., *Mimusops elengi* L., *Shorea robusta* C.F.Gaertn., *Tectona grandis* L.f., *Terminalia chebula* Retz., and *Toona ciliata* M. Roem. Common in the BWS were edible species of fruit trees: *Aegle marmelos* (L.) Correa, *Carica papaya* L., *Dillenia indica* L., *Elaeocarpus floribundus* Blume, *Mangifera indica* L., *Phyllanthus emblica* L., *Syzygium cumini* (L.) Skeels, *Tamarindus indica* L., and *Zizyphus jujuba* Mill. Other common species of the sanctuary were *Bombax ceiba* L., *Cinnamomum tamala* (Buch.-Ham.) T.Nees & C.H.Eberm., *Ficus benghalensis* L., *F. religiosa* L., *Murraya koenigii* (L.) Spreng., and *Oroxylum indicum* (L.) Kurz. Among the bamboos, *Bambusa vulgaris* Schrad. ex J.C.Wendl. and *Dendrocalamus hamiltonii* Nees & Arn. ex Munro were common in the forest areas. Dominant palm species of the sanctuary were *Areca catechu* L., *Caryota urens* L., and *Licuala peltata* Roxb. ex Buch.-Ham.

Among the lianas, some commonly occurring species recorded were *Combretum indicum* (L.) DeFilipps, *Entada gigas* (L.) Fawc. & Rendle, *Phanera glauca* Wall. ex Benth., *Thunbergia grandiflora* Roxb., and *Tinospora crispa* Miers.

Flowering and fruiting phenology (Figs 6, 7). For trees, the flowering was mostly in March (pre-monsoon) to August (post-monsoon), but peaked in June; the peak in fruit production was in the late dry season (August to December). For lianas, flowering peaked in April to July (pre-monsoon and monsoon) and fruit production peaked in the late dry season (August to December).

IUCN Red List categories. Of all species recorded, only 1 tree species (Vulnerable) is threatened; all other species are categorized as Least Concern, Data Deficient, or are Not Evaluated.

Discussion

Our results indicate a rich flora in the BWS, possibly due to the region's physiography of undulating hills and hillocks and tropical to subtropical climate.

Recently, Barbuiya (2013a) recorded several species from the BWS that we failed to find. These are: *Actinodaphne obovata* (Nees) Blume, *Balakata bacata* (Roxb.) Esser, *Catunaregam spinosa* (Thunb.) Tirveng., *Cinnamomum bejolghota* (Buch.-Ham.) Sweet, *Croton joufra* Roxb., *Meliosma simplicifolia* (Roxb.) Walp., *Prismatomeris tetrandra* K. Schum., and *Toxicodendron bimannii*. Some earlier collections were also found in the herbarium of Botanical Survey of

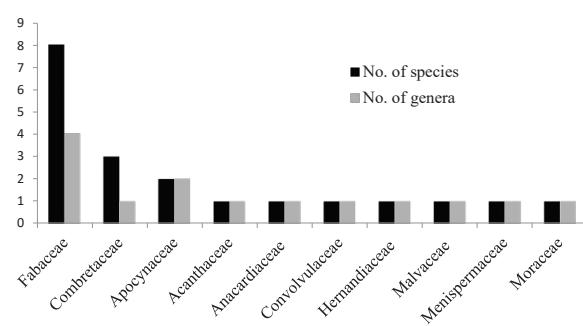

Figure 5. Dominant liana families with number of species and genera.

India at ASSAM, which could also not be traced in the field. These are: *Abroma augustum* (L.) L.f., *Archidendron clypearia* (Jack) I.C. Nielsen, *Camellia oleifera* C. Abel, *Dalbergia stipulacea* Roxb., *Dendrocnide sinuata* (Blume) Chew, *Hodgsonia macrocarpa* (Blume) Cong., *Octea lancifolia* Mez, *Sterculia villosa* Roxb. ex Sm., and *Styrax serrulatus* Roxb. This might be due to their localized distribution or their rarity in the sanctuary. Additional fieldwork is needed to locate these species in BWS.

Although, most parts of the BWS is still virgin, human habitations in and around the sanctuary exist (8 in East Block; 19 in West Block; Anonymous 2006). With an increasing population, villagers' demands on the forest and its products are increasing with the collection of bamboos, canes, and timber. Clearing of forests for the cultivation of areca nut, beetle leaf, pineapple, and banana is leading to a loss of biodiversity at the forest margins. Massive habitat loss in the buffer zone also

results in species destructions. Other human activities, like road construction, cutting of forests for *jhum* (shifting) cultivation, areca nut plantation etc., along with some natural phenomena like landslides due to heavy rain, thunderstorms, and hailstorms, are also serious threats to biodiversity. Therefore, there is an urgent need for developing and implementing conservation strategies for the BWS.

Acknowledgements

We extend our sincere thanks to the Divisional Forest Officer, Cachar Division, Assam for granting permission to carry out this study. Special thanks are due to Mr D.J. Nath, Forest Range Officer of Kalain Forest Division, for his kind help. We are also thankful to the Head, Botanical Survey of India (ASSAM, and CAL) for permitting us to consult the Institutes' herbaria and libraries. The GUBH herbarium is also gratefully acknowledged. Our gratitude goes to the Dean, School of Life Sciences, Assam University, Silchar and the Head, Department of Life Science and Bioinformatics, Assam University, Silchar for providing facilities. The first author (AB) acknowledges the University Grant Commission (UGC), New Delhi for financial support under the UGC-MRP scheme.

Authors' Contributions

AB carried out fieldwork for collecting specimens, identified the specimens, and drafted the manuscript. DB also took part in field and coordinated the work. Both authors interpreted the results, as well as read and approved the final content of the manuscript.
