### Abstract

The sea anemone *Calliactis tricolor* (Le Sueur, 1817) is an ecologically important member of the benthic community in coastal and coral reefs of the tropical Atlantic, particularly for their propensity to establish mutualistic symbiotic relationships with hermit crabs. This species is presumably distributed throughout the Gulf of Mexico; however, it had never been recorded in the southwestern part of the Gulf. Here we document the first record of *C. tricolor* in 2 coral reef localities of the Veracruz reef system, Mexico, and update the number of species of sea anemones known for the region.

### Key words

Anthozoa; sea anemone; coral reefs; epibiont; hermit crab.

### Introduction

*Calliactis tricolor* (Le Sueur, 1817) is one of the most well-known sea anemone species inhabiting coral reefs and shallow coastal waters of the western Atlantic. Particular attention has been paid to this species due to its propensity to establish close mutualistic symbiotic relationships with hermit crabs, such as *Pagurus pollicaris* Say, 1817, *Dardanus venosus* (Milne-Edwards, 1848), *Dardanus fucusus* Biffar and Provenzano, 1972, and *Petrochirus diogenes* (Linnaeus, 1758), among other crustaceans (Cutress and Ross 1969, Cutress et al. 1970,

Mariscal 1972, López-Victoria et al. 2004).

In this symbiotic relation, 1 to several individuals of *C. tricolor* live as epibionts on gastropod mollusk shells occupied by hermit crabs. Sea anemones are known to protect hermit crabs from their natural predators, such as the crab *Calappa flammea* (Herbst, 1794) and the octopus *Octopus joubini* Robson, 1929 (McLean and Mariscal 1973, Bach and Herrnkind 1980, McLean 1983). Hermit crabs, on the other hand, provide protection for *C. tricolor* against predators such as the sea star *Echinaster spinulosus* Verrill, 1869 and the fireworm *Hermodice*

*carunculata* (Pallas, 1766) (Brooks and Gwaltney 1993). In addition, sea anemones are benefited by having a hard substrate on which to attach, and by the interception of food particles while crabs feed (Bach and Herrnkind 1980).

The known distribution of *C. tricolor* ranges from North Carolina and the northeastern coast of Gulf of Mexico to Brazil, including eastern and southern Caribbean Sea (Carlgren and Hedgpeth 1952, Zamponi et al. 1998). Although this species has been reported in the Campeche Bank and in the northwestern Gulf of Mexico (González-Muñoz et al. 2013), it had never been recorded in the southwestern part of the Gulf, despite several surveys documenting local sea anemone diversity within the last 30 years, particularly in the Veracruz reef system (VRS) (González-Muñoz et al. 2015a).

Jordán-Dahlgren (2002) suggested limited ecological connectivity between the reefs of the Caribbean and the Campeche Bank with the reef systems from the southwestern Gulf of Mexico. He observed a westward decreasing gradient pattern in gorgonian diversity and abundance from the Yucatan straits to the southwestern Gulf of Mexico, as well as a northward decreasing gradient pattern in the southwestern Gulf of Mexico, from the VRS to the Tuxpan and Isla Lobos reef systems. This limited connectivity could possibly explain the absence in the VRS of some sea anemone species that, like *C. tricolor*, are commonly found in the reefs of the Caribbean and the Campeche Bank, such as *Condylactis gigantea* (Weinland, 1860), and *Lebrunia neglecta* Duchassaing & Michelotti, 1860 (González-Muñoz et al. 2015a).

In the present study, we document the presence of *C. tricolor* in 2 coral reef localities of the VRS. Although *C. tricolor* could have been overlooked for years in the region, it is possible that this species was absent in this coral system until recently, suggesting potential connectivity between distant reef systems in the Gulf of Mexico.

This record increases the number of sea anemone species known for the VRS and contributes with original data for biogeographic studies of sea anemones distribution in the Gulf of Mexico by filling gaps of the known distribution range of *C. tricolor*.

## Methods

During a field study in May 2015, 1 individual of *Calliactis tricolor* was observed attached to a shell of the gastropod mollusk *Fasciolaria tulipa* (Linnaeus, 1758) occupied by the hermit crab *Petrochirus diogenes*, in Isla de Enmedio reef, which is 1 of the 25 coral reef localities of the VRS (Chávez et al. 2007). The mollusk shell was apparently very old and covered with sand, algae, small stones, and crustose coralline algae. The sea anemone was photographed, collected, relaxed in a 5% MgCl<sub>2</sub> seawater solution, and subsequently fixed in 10% seawater formalin to be transferred to the laboratory for identification. The specimen was collected under consent of Mexican law, with a collecting permit approved

by the Comisión Nacional de Acuacultura y Pesca (no. 07332.250810.4060).

A second individual of *C. tricolor* was observed in May 2016, attached to a shell of *Sinistrofulgur sinistrum* (Hollister, 1958) occupied by the hermit crab *Dardanus fucosus*, in La Gallega reef, VRS. On this occasion, the anemone was measured and photographed, but not collected. The taxonomic identification of the observed specimens was based on external anatomy, following Carlgren and Hedgpeth (1952) and González-Muñoz et al. (2013).

Previous data on distribution of *C. tricolor* were obtained from main online biodiversity and biogeographic databases, including the Global Biodiversity Information Facility (GBIF 2017), the Oceanographic Biogeographic Information System (OBIS 2017), and Hexacorallians of the World (HoW) (Fautin 2013), as well as those from published articles, and 2 doctoral theses (Corrêa 1964, Gusmão 2010). As some distributional records from the online databases were incomplete, the names of the localities were searched and added for those records which only had data on geographic coordinates. Alternatively, geographic coordinates were inferred from those records which had only locality name. Duplicated records from different sources, records without locality names and geographic coordinates were disregarded, as well as those without reference for the specialist who identified the species by observation or specimen examination. These data (Appendix, Table A1) were used to construct a map with the distribution of *Calliactis tricolor* in the West Atlantic.

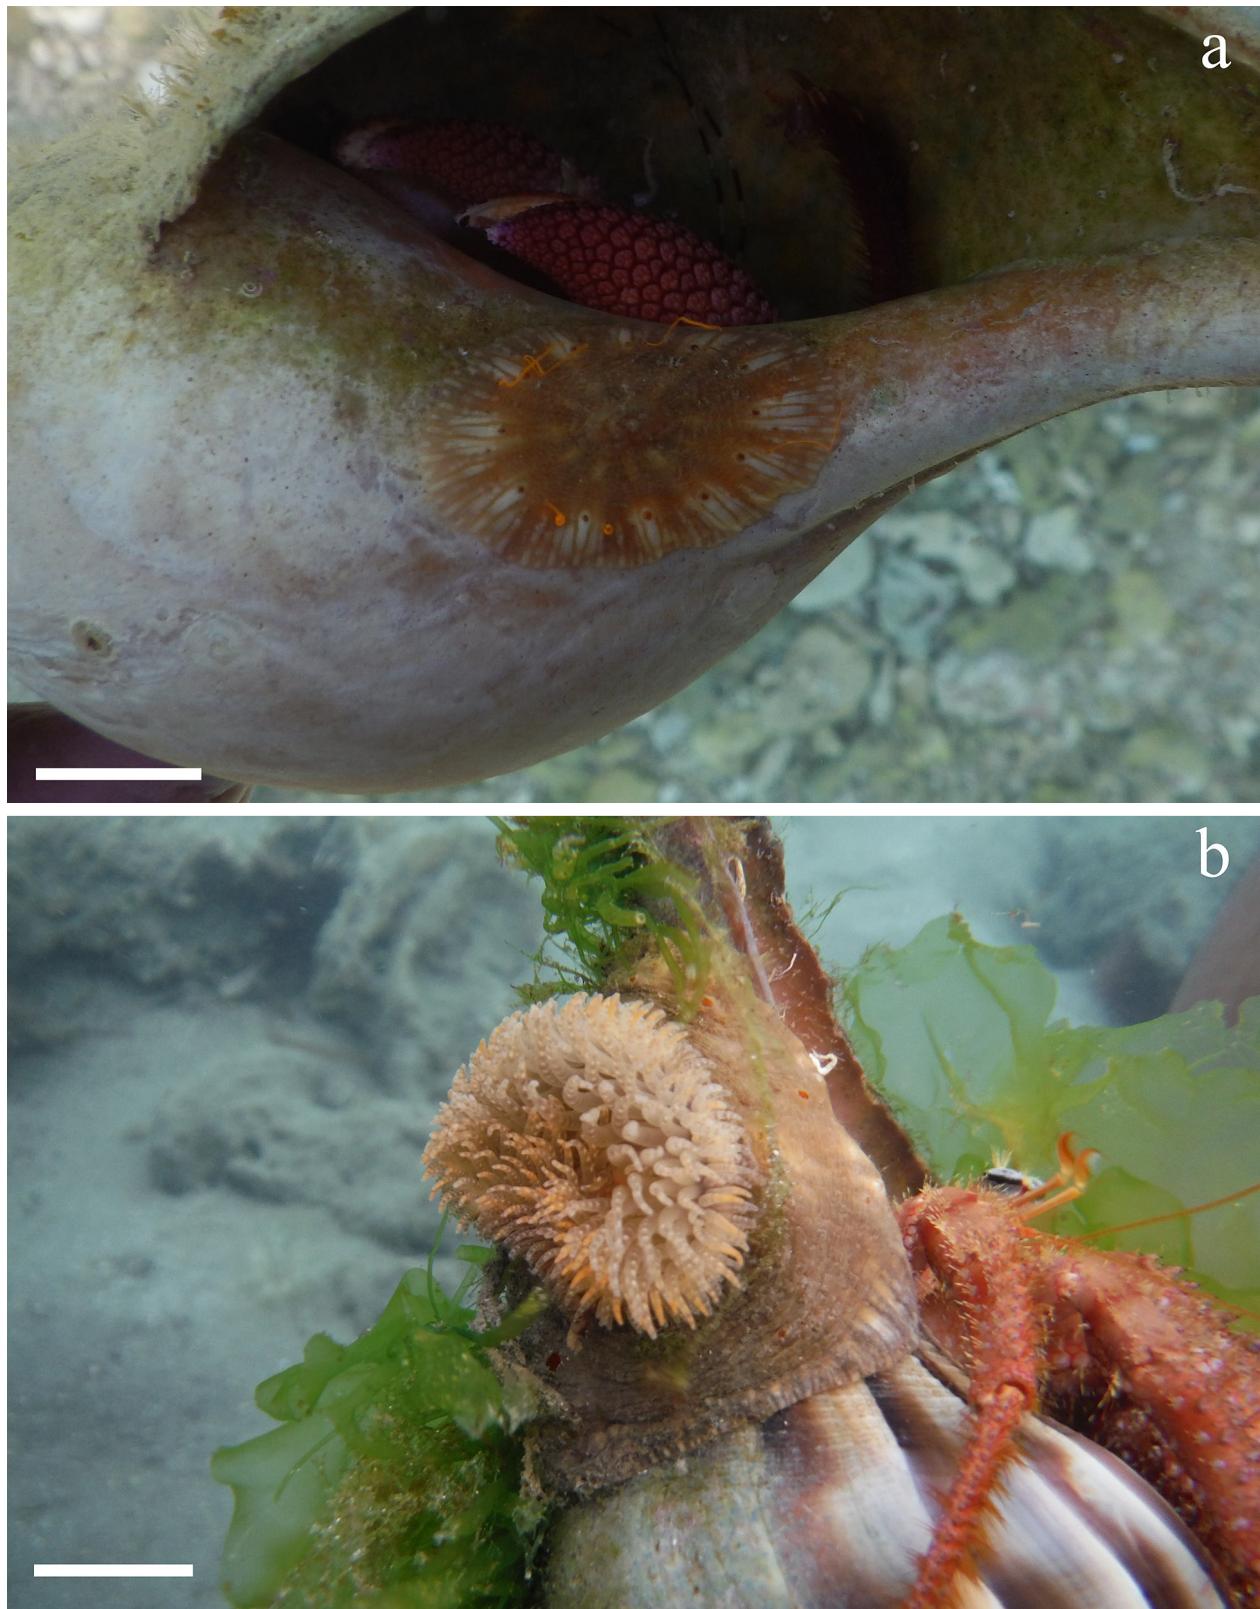

## Results

**Material examined.** 1 specimen, 7 May 2015, Isla de Enmedio reef (19°05.5' N, 095°58.2' W), collected by José Luis Tello-Musi, deposited in the scientific collection of Cnidarios del Golfo de México y el Mar Caribe, Universidad Nacional Autónoma de México (UNAM) (voucher code: YUC-CC-254-11-001378).

**Identification.** Collected and observed specimens were identified as *Calliactis tricolor* (Le Sueur, 1817) (Fig. 1a, b).

Observed features of the collected specimen (Fig. 1a) are the following: column smooth but rough in appearance, orange-red to beige, with small longitudinal white spots in the proximal column, relative to the mesenterial insertions. Two rows of dark-orange cinclides in the proximal column and close to the limbus; first row with 12 cinclides and second with 24, arranged as follows: 2 smaller cinclides of the second row between each pair of the 12 larger cinclides of the first row. Bright-orange acontia protruding from cinclides and from the oral disc. Pedal disc about 27 mm in its larger diameter.

The second specimen (not collected) was observed with the oral disc and tentacles completely expanded and presented the following diagnostic features (Fig. 1b): oral

**Figure 1.** Specimens of *Calliactis tricolor* found in the Veracruz Reef System, southwest Gulf of Mexico. **a)** Specimen attached to a shell of *Fasciolaria tulipa* occupied by *Petrochirus diogenes* in Isla de Enmedio reef. **b)** Specimen attached to a shell of *Sinistrofulgur sinistrum* occupied by *Dardanus fucusus*, in La Gallega reef. Scale bar = 10 mm.

disc smooth, beige to pale-orange and translucent. Tentacles smooth, slender, moderately short, tapering distally, beige to pale-orange, with longitudinal rows of white dots along its entire length, and sometimes with orange flashes at the tips. Column cylindrical, trumped-shaped

when expanded and dome-shaped when contracted, divided into capitulum and scapus. Capitulum short, beige, translucent; scapus robust, wrinkled-texture, beige to pale-orange, and with short white longitudinal spots and 2 rows of dark-orange cinclides proximally, which

**Figure 2.** Known distribution of the sea anemone *Calliactis tricolor*. Gray dots represent previous records; red triangles represent the new records in the southwest Gulf of Mexico, at the Veracruz reef system.

are of different sizes. Pedal disc about 47 mm in its longer diameter.

**Data on distribution of *Calliactis tricolor*.** We obtained 297 records of *C. tricolor* from GBIF (2017), OBIS (2017), HoW (Fautin 2013), and published articles, of which 63 were disregarded following the criteria mentioned above; thus, 234 previous records were considered (Appendix, Table A1). Figure 2, based on these data, shows the known distribution of *C. tricolor* in the western Atlantic.

## Discussion

The collected specimen was found with the oral disc and tentacles completely contracted, and they remained so during relaxation process. Thus, it had to be fixed in this position. However, external anatomy and coloration of the column are sufficient for identification, and the specimen corresponded to the diagnostic features of *Calliactis tricolor*. The taxonomic features of the observed

(not collected) specimen also fitted well with *C. tricolor*, particularly in the pattern coloration of the column, cinclides, oral disc, and tentacles.

In her study on sea anemones symbiotic with hermit crabs, Gusmão (2010) mentioned that *C. tricolor* is the only species of the genus distributed in the western Atlantic. However, there are few records of *Calliactis polypus* (Forsskål, 1775) in the northern Gulf of Mexico (Dawson 1966), the eastern coast of the USA, and in Guyana (OBIS 2017, GBIF 2017), although this species is mainly distributed in the Red Sea, Hawaii, French Polynesia, Australia, South Africa, East Africa, Maldives, Cape Verde Island, Japan, Galapagos, and the Pacific coast of Panamá (Garese et al. 2009, Gusmão 2010). Live specimens of *C. tricolor* and *C. polypus* can be easily distinguished by the coloration of the cinclides in the proximal column, being dark-red to dark-orange in the former and white in the latter (Gusmão 2010, González-Muñoz et al. 2013). As *C. polypus* has been reported only once in the Gulf of Mexico (Dawson 1966), it is possible

that the report of its presence is result of a probable misidentification, but this needs to be corroborated with the review of those specimens.

Because the anomuran crabs *Dardanus venosus*, *D. fuscus*, *P. diogenes*, *P. pollicaris*, as well as the brachyuran crabs *Stenocionops furcatus* (Olivier, 1791), *Callinectes danae* Smith, 1869, *Hepatus epheliticus* (Linnaeus, 1763), and *Hepatus pudibundus* (Herbst, 1785) are among the crustacean species that have been documented in association with *C. tricolor*, and all of them have been reported along the Mexican Atlantic coast (Arenas-Fuentes and Ramos-Rivera 2017, León-García and Ramos-Rivera 2017, Raz-Guzmán and Ramos-Rivera 2017, Rodríguez-Almaráz and Ramos-Rivera 2017), the interaction between these crustaceans and the sea anemone, as well as its dispersal along the coast of Gulf of Mexico could have favored the presence of *C. tricolor* into the region.

The nearest previous record of *C. tricolor* in the Gulf of Mexico, at a site between Tamaulipas, Mexico, and Texas, USA, about 50 km to the nearest coast (Gusmão 2010) is about 635 km north from the new records documented here. The second nearest previous record is about 650 km east, recorded by González-Muñoz et al. (2013) in Serpientes reef, about 50 km from the nearest coast. The new record here documented fills a gap of over 1500 km of coastline in the known distribution of *C. tricolor* (Fig. 2).

Currently, there are 21 sea anemone species formally reported in the Atlantic coast of Mexico (González-Muñoz et al. 2012, 2013, 2015a, 2015b, 2018), of which 15 have been documented in the VRS (González Muñoz et al. 2015a). The occurrence of *C. tricolor* increases the number of the known sea anemone species for the VRS to 16.

## Acknowledgements

Expedition was partially financed by grants to NS from the Harte Research Institute (Biodiversity of the southern Gulf of Mexico) and CONABIO (NE018; Actualización del conocimiento de la diversidad de especies de invertebrados marinos bentónicos de aguas someras [ $< 50$  m] del sur del Golfo de México). Felipe de Jesús Cruz-López (FES-Iztacala, UNAM) and Gabriel Cervantes (UMDI-Sisal, UNAM) helped with mollusk and hermit crab species identification, respectively. Second author is grateful to the Programa de Becas Postdoctorales Internas Latinoamericanas of the Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Argentina. We thank the 2 reviewers whose comments helped us to improve this manuscript.
