Abstract

Fifteen specimens (56.4–112.9 mm standard length) of *Aseraggodes kobensis* (Steindachner, 1896) were collected from Malaysia. This species was previously known from southern Japan to the Gulf of Thailand and western India, and the new records expand its range south in the Western Pacific by about 750 km. A detailed description is given for the specimens, the first collected from Malaysian waters.

Keywords

Biogeography, distribution, demersal fish, marine fish, range extension, South China Sea.

Introduction

The Soleidae is the largest family in Pleuronectiformes and has 183 valid species (Fricke et al. 2019) in 32 genera (Froese and Pauly 2019). These fishes are known as “ikan lidah” in Malaysia, where there are 17 species in 10 genera (Annie and Albert 2009; Ambak et al. 2012; Froese and Pauly 2019). The genus *Aseraggodes* Kaup, 1858, which is the most species-rich soleid genus with 53 valid species (Munroe 2001; Randall et al. 2013), is characterized by the following combination of characters: snout without a distinct hook, mouth slightly contorted, caudal fin separated from dorsal and anal fins, dorsal and anal-fin bases without pores, and pectoral fins absent (Munroe 2001; Randall and Bartsch 2005).

During fieldwork near Pulau Bidong, Terengganu in 2015, specimens of an unidentified sole were collected. Subsequently, additional specimens of the same species were collected by us from fish landing ports at Chendering (Kuala Terengganu) and Tok Bali (Kelantan). Specimens were collected from bottom trawlers, which is the prime fishing gear in Malaysia (Seah et al. 2016). The specimens are identified here as *Aseraggodes kobensis* (Steindachner, 1896), a species previously known from Japan and the Philippines to Chantha Buri, northern Gulf of Thailand and western India (Imamura 2013; Nair and Gopalakrishnan 2013). Accordingly, the present specimens represent the first records from Malaysia and southernmost records for the species. *Aseraggodes*

kobensis joins *A. senoui* Randall & Desoutter-Meniger, 2007 as only the second species of *Aseraggodes* collected from Mabul Island, Sabah, Malaysia.

Methods

All fish catches were sorted in accordance with the standard protocol by Sparre and Venema (1998), and the procedures for fixation, photography, and preservation of specimens followed Seah et al. (2011). Methods for counting and measuring generally followed Hubbs and Lagler (2004), and the terminology of morphological features and descriptions were modified from Randall et al. (2013). Specimens were measured to the nearest 0.1 mm using digital calipers (Mitutoyo, Japan); the abbreviation SL = standard length, HL = head length. Species identifications followed Nakabo (2002), Imamura (2013),

and Jeong (2017). All specimens were deposited in the South China Sea Repository and Reference Center, Universiti Malaysia Terengganu, Malaysia (UMTF).

Sheikh Abdul Kadir and J. Okamoto collectors, 10 Oct. 2018, 4 spec. (UMTF 8502, 82.0 mm SL; UMTF 8503, 70.1 mm SL; UMTF 8504, 94.7 mm SL; UMTF 8505, 64.1 mm SL).

Identification. Counts and measurements are given in Table 1. A fresh specimen (UMTF 8502) is shown in Figure 1. The specimens collected from Malaysia were identified from the following combination of characters, which closely match the diagnostic features given by Nakabo (2002), Imamura (2013), and Jeong (2017) for *A. kobensis*: body moderately elongate; mouth small and slightly contorted; bases of dorsal and anal fins without pores; pectoral fin absent on both sides; pelvic fin on ocular side slightly longer than that on blind side, close

together and not joined to anal fin; anterior nasal tube short, not reaching to lower eye anterior margin on ocular side; caudal fin not connected to dorsal and anal fins; body uniformly pale brown with some faint dark brown blotches on ocular side, uniformly white on blind side; dorsal and anal fins uniformly brownish when fresh.

Description. Body moderately elongate; ventral profile of head posterior to mouth slightly convex; medial of upper eye in front of the anterior of lower eye; horizontal level of upper end of gill opening about one orbit diameter below lower eye, the ocular side end slightly curved, with a scaleless membrane, and tubular in some individuals; caudal peduncle present, posteriormost dorsal and anal fins ray separated from base of caudal fin ray; jaws weakly curved; maxilla extending slightly posterior to anterior edge of lower eye; blind side of upper and lower jaws with a narrow band of close-set villiform teeth; anterior nostril on ocular side not reaching lower eye when nostril laid backward, its length less than eye diameter; no cirri on edge of gill opening on either side; eyes not protruding, cover without scales; scales strongly ctenoid on ocular and blind sides, extending broadly onto medial and anterior parts of eyes; front of snout and chin on blind side without low fleshy papillae; lateral line straight on

both sides of body, ending on ocular side about one eye diameter posterior to upper eye; scales not extending onto dorsal and anal fins on either side; scales present on caudal fin base; origin of dorsal fin anterior to upper eye; first anal fin ray level with base of 19th to 21st dorsal fin ray; caudal fin strongly rounded; pelvic fins adjacent on ventral margin of body, the ocular-side fin a little anterior; second and third pelvic fin rays longest, reaching base of second anal fin ray; anus anterodorsal and adjacent to first anal ray. When fresh (Fig. 1), on ocular side body pale brown with scattered darker brown speckles, on blind side generally pale or rarely whitish with an obscure brown tinge adjacent to dorsal and anal fins; scales on ocular side narrowly edged with dark brown; fin rays paler brown than body; membranes translucent.

Discussion

Aseraggodes kobensis was originally described by Steindachner (1896), as *Solea (Achirus) kobensis*, based on a mature specimen collected from Kobe, Hyogo Prefecture, Japan. Ochiai (1984) referred the species to *Aseraggodes*, with which it shares common features with other *Aseraggodes* species. Although *A. kobensis* is most similar to *Aseraggodes umbratilis* (Alcock 1894), known from the Indian Ocean, the latter differs from *A. kobensis* in having smaller eyes, no cirri on the front of the snout, a longer caudal peduncle, and a shorter caudal fin (Nair and Gopalakrishnan 2013).

Aseraggodes kobensis has previously been recorded from the northwestern Pacific Ocean from Japan to the northern Gulf of Thailand, including Taiwan, Hong Kong, Vietnam, and the Philippines, and from the western Indian Ocean (Imamura 2013; Nair and Gopalakrishnan 2013; Jong 2017; Fricke et al. 2019). The presence of *A. kobensis* in Malaysia was expected, and our new records narrow the gap of its distribution in the Indo-West Pacific Ocean. Indeed, *Aseraggodes kobensis* is common off the east coast of Peninsular Malaysia, where it is mainly caught by bottom trawler together with species of Leiognathidae, Bothidae, and crustaceans. However, *A. kobensis* is not found in local markets; its small size makes it unmarketable, and thus it is processed into fertilizer. In Malaysia, untargeted fish species often receive relatively little attention compare with commercial fishes in ichthyological studies, make the marine fishes remain poorly known (Mat Jaafar et al. 2019; Seah et al. 2016). *Aseraggodes kobensis* is a small species and Imamura (2018) recorded a maximum standard length of 10.0 cm. However, UMTF 6460 (112.9 mm SL) is now the largest known specimen of this species. The Malaysian specimens represent the southernmost records of *A. kobensis* in the South China Sea.

Acknowledgements

We are grateful to staff of the South China Sea Repository and Reference Center, Universiti Malaysia Terengganu

for their support during Jo Okamoto's internship at the university. Special thanks go to Mohd Rodila bin Ibrahim for his assistance during Jo Okamoto's stay and the fish survey. G. Hardy (Ngunguru, New Zealand) checked the English manuscript. Jo Okamoto gratefully acknowledges a "Tobitate! Young ambassador program" scholarship provided by Ministry of Education, Culture, Sports, Science and Technology, Japan. Y.G. Seah thanks the School of Fisheries and Aquaculture Sciences for maintaining an annual ichthyofaunal survey and Yuzwan bin Mohamad for generating the distribution map. This study was supported in part by the Kagoshima University projects "Establishment of Research and Education Network on Biodiversity and Its Conservation in the Satsunan Islands" (adopted by the Ministry of Education, Culture, Sports, Science and Technology, Japan) and "Island Research" (to H. Motomura).

Authors' Contributions

YGS and TNAMJ designed the plan. YGS, TNAMJ and HM identified the species. JO and STSAK collected data. JO edited the photographs of the specimens. JO wrote the manuscript and made the measurements. All authors reviewed, finalized, and approved the manuscript.
