Abstract

We describe new records of *Trichothraupis melanops* in five municipalities of Rio Grande do Sul, Brazil. The birds were detected in sporadic expeditions in the Serra do Sudeste and Campanha Gaúcha regions by direct visualization and vocal recognition. One of these records, next to the border with Uruguay, is the southernmost known location for the species in Brazil. This record expands the geographic range of the species in Brazil south by 170 km. We believe that these occurrences are seasonal displacements and do not represent a colonization front with resident populations.

Keywords

Frutero Corona Amarilla, geographic distribution, *Lanio melanops*, Pampa biome birds, seasonal displacements, tiê-de-topete.

Introduction

Trichothraupis Cabanis, 1850, is a monospecific genus consisting of the Black-goggled Tanager, *Trichothraupis melanops* (Vieillot, 1818). The species has forest habitat, living in the understory of old-growth and second-growth forests (Fávaro and Anjos 2005; BirdLife International 2016). Individuals are seen alone, in pairs, or in small groups. They constitute mixed-species bird flocks, acting as a nuclear species (Faria and Rodrigues

2009). They mainly feed on arthropods and occasionally on fruits (Hilty 2019). This tanager is apparently resident throughout its area of occurrence, considered scarce to locally abundant (Belton 1994; Hilty 2019). The conservation status of this species is Least Concern (BirdLife International 2016).

Trichothraupis melanops occurs in Brazil from Bahia to Rio Grande do Sul, and also in Argentina, Paraguai, Bolivia, and Peru (BirdLife International 2016). There is a lack of documental evidence about its occurrence in

Uruguay (Azpiroz et al. 2012). In the state of Rio Grande do Sul, it occurs from the Southern Brazilian Plateau as far as the northern border of the Central Depression, with records in the northern part of the Coastal Plain. Costa (2005) ruled out the possibility of it occurring in the Campanha region.

The originally accepted southern limit of distribution of *T. melanops* in Brazil was Viamão municipality. Individuals have been recorded in two protected natural areas there: the Itapuã State Park (Belton 1984, 1994) and the Banhado dos Pachecos Wildlife Refuge, a few kilometers north (Accordi and Hartz 2006).

Marateo et al. (2009) mentioned two records of *T. melanops* (2004 and 2005) in El Palmar National Park, Colón municipality, Entre Ríos Province, Argentina. These are the southernmost records for the species. However, the distribution map suggested by BirdLife International and adopted by IUCN (BirdLife International 2016) was not altered to include those records.

We document new records of *T. melanops* in the extreme southern limits of Brazil, establishing a new southern limit of occurrence in Brazil for *T. melanops*.

Methods

Between 2015 and 2018 we and our collaborators performed sporadic research/photographic expeditions in the regions Serra do Sudeste and Campanha Gaúcha, Rio Grande do Sul, Brazil. The purpose of these expeditions was to elaborate bird species lists and make photographic records.

The birds were recognized by direct visualization and vocal recognition. In all localities the species was casually recorded and the individuals were photographed. No attraction methods (e.g. playback or baits) were used to record the birds. The minor distance between two localities of data collection was 41 km.

One audio recording of *T. melanops* was obtained using a smartphone coupled with a parabolic microphone

reflector (SONY PBR-300). The vocalization of two individuals was captured with the voice recorder app HI-Q MP3 REC 2.7.1 in high-fidelity Waveform Audio File Format (encoding: PCM uncompressed; sample rate 48000 Hz; sample size: 16 bits). Vocalizations were emitted spontaneously (contact calls) while birds foraged. A sonogram and spectrogram were obtained with the sound editor software Raven Lite 2.0.1. (Bioacoustics Research Program. 2016) (Fig.1).

The Serra do Sudeste, also named Escudo Sul-Rio-Grandense, is a dissected plateau, characterized by undulating relief of elevations between 200 and 500 m. The vegetation type is grassland-forest mosaic with the presence of steppe, savanoid vegetation and semi-deciduous seasonal forest (Teixeira et al. 1986; Pillar et al. 2009). The region's climate type is humid subtropical climate (Cfa) according to the Köppen classification (Alvares et al. 2013).

The Campanha region is characterized by flat to gently undulating topography with elevations between 140 and 220 m (Ab'Saber 1969). Its vegetation presents a predominance of grasslands permeated with shrublands and low growing forests that are poor in species richness and restricted to banks of watercourses (Teixeira et al. 1986). The region's climate type is also considered (Cfa) (Alvares et al. 2013).

Geographic coordinates were obtained using a Garmin GPSMAP64 GPS receiver using the WGS84 datum. To create the geographic distribution map (Fig. 2) we used ArcGIS v. 10.2.2 (ESRI 2014). We inserted the IUCN suggested geographic range (BirdLife International 2016), the points of the previous southernmost known locations (Belton 1994; Marateo et al. 2009), and the new records. Finally, we drew a minimum convex polygon, as indicated by the IUCN to calculate the Extent of Occurrence (EOO; IUCN Red List Technical Working Group 2019), to encompass our new records, the southernmost known occurrence of the species (Marateo et al. 2009), and the geographic range suggested by IUCN (BirdLife International 2016).

We searched for occurrence records in the following databases: Global Biodiversity Information Facility (<https://www.gbif.org>), SpeciesLink (<http://www.splink.org.br>), eBird (<https://ebird.org>), EcoRegistros (<http://www.ecoregistros.org>), Xeno-Canto (<https://www.xeno-canto.org>), WikiAves (<https://www.wikiaves.com.br>), and Portal de Periódicos Capes (<http://www.periodicos.capes.gov.br>).

Results

New records. Brazil • 1 adult ♂; Rio Grande do Sul, São Lourenço do Sul, Picada Quevedos; 31°18.65'S, 052°

17.33'W; 20 Jun. 2015; observed by GCG and Raphael Kurz (Fig. 3A; photographic record available at Wiki-Aves as WA1731422); solitary individual observed at edge of semi-deciduous seasonal forest fragment within a mosaic of agricultural areas with abandoned pastures and forest fragments (Fig. 4A). • 1 adult ♀; Rio Grande do Sul, Sentinela do Sul, Passo Grande; 30°40.05'S, 051°36.96'W; 9 Jul. 2017; observed by Julianita D. Moraes (Fig. 3B; photographic record available at Wiki-Aves as WA2631560); in mixed-species flocks in the high canopy of *Eucalyptus* trees, in an area characterized by predominance of bovine cattle pastures, permeated

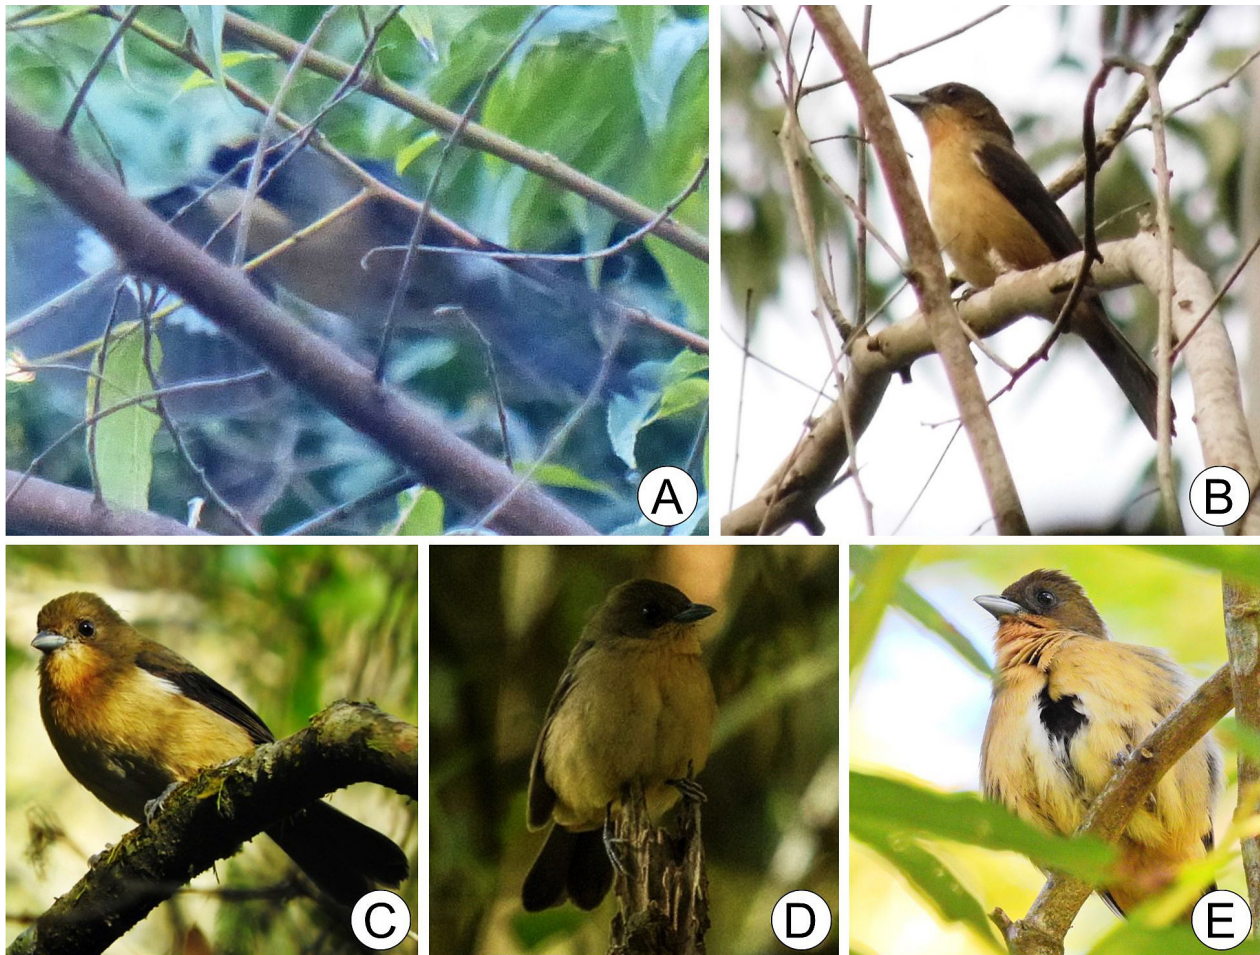

Figure 3. Photographic records of the individuals reported in the following municipalities: **A.** São Lourenço do Sul. **B.** Sentinela do Sul. **C.** Aceguá. **D.** Pelotas. **E.** Candiota. Photographs by GCG, Julianita D. Moraes, Adolph Wall, FPJ, and Rudimar de Matos, respectively.

with secondary forest fragments and silviculture forests (Fig. 4B). • 1 adult ♀; Rio Grande do Sul, Aceguá, Colônia Pioneira; 31°46.55'S, 054°02.35'W; between 3 Jun. and 1 Set. 2018; observed by Adolf Wall and MSW (Fig. 3C; photographic records available at WikiAves as WA2992271; WA2993370; WA3011482; WA3016961; WA3026153). Possible all the records are of the same female, for it was seen for the first time in the riparian forest of Jaguarão Chico stream; all the following records are within 200 m of site, in the garden trees of a farm's main house. The locality is characterized by agricultural production, flat terrain and mainly grasslands with low riparian forests, typical of the Pampa Biome (Fig. 4C). • 2 adults ♀; Rio Grande do Sul, Pelotas, Cascata; 31°36.91'S, 052°30.43'W; 8 Jun. 2018; observed by FPJ (Fig. 3D; photographic record available at WikiAves as WA2998346; audio recording available at Xeno-canto as XC484407); foraging in mid-level of forest edge with a couple of *Tachyphonus coronatus* (Vieillot, 1822); apparently, all others followed the adult male of this latter species; on a road that crosses a degraded semi-deciduous forest fragment, near a couple of human houses (Fig. 4D). • 1 adult ♀; Rio Grande do Sul, Candiota, Vila Operária; 31°27.35'S, 053°38.93'W; 16 Aug. 2018; observed by Rudimar de Matos, (Fig. 3E; photographic

record available at WikiAves as WA3074263); in mixed-species bird flock near Candiota stream; riparian vegetation of shrubs and small trees, between grasslands and *Eucalyptus* plantations (Fig. 4E).

Identification. *Trichothraupis melanops* is characterized by its conspicuous plumage in relation to other species of tanagers. The male presents a dark grey back, black wings and tail and cinnamon underparts. It also presents an extense yellow crest, which contrasts with a black mask, and a bluish beak. The female does not present the black mask and it does present a smaller yellow crest. The immature does not present yellow on the crown. Male and female present a white wingband, visible in flight (Fig. 3A) (Hilty 2019; Narosky and Yzurieta 2010; Timm and Timm 2016).

Discussion

The avifauna of Serra do Sudeste and Campanha Gaúcha has been studied since the 1970s (Belton 1984, 1994; Mauricio and Dias 1998, 2001; Efe et al. 2010; Corrêa et al. 2012; Corrêa et al. 2013; Seixas et al. 2014; Bergmann et al. 2015) without finding *T. melanops*. Hermann von Ihering, who lived for seven years (1885–1892) in São Lourenço do Sul municipality (Lopes and Podgorny

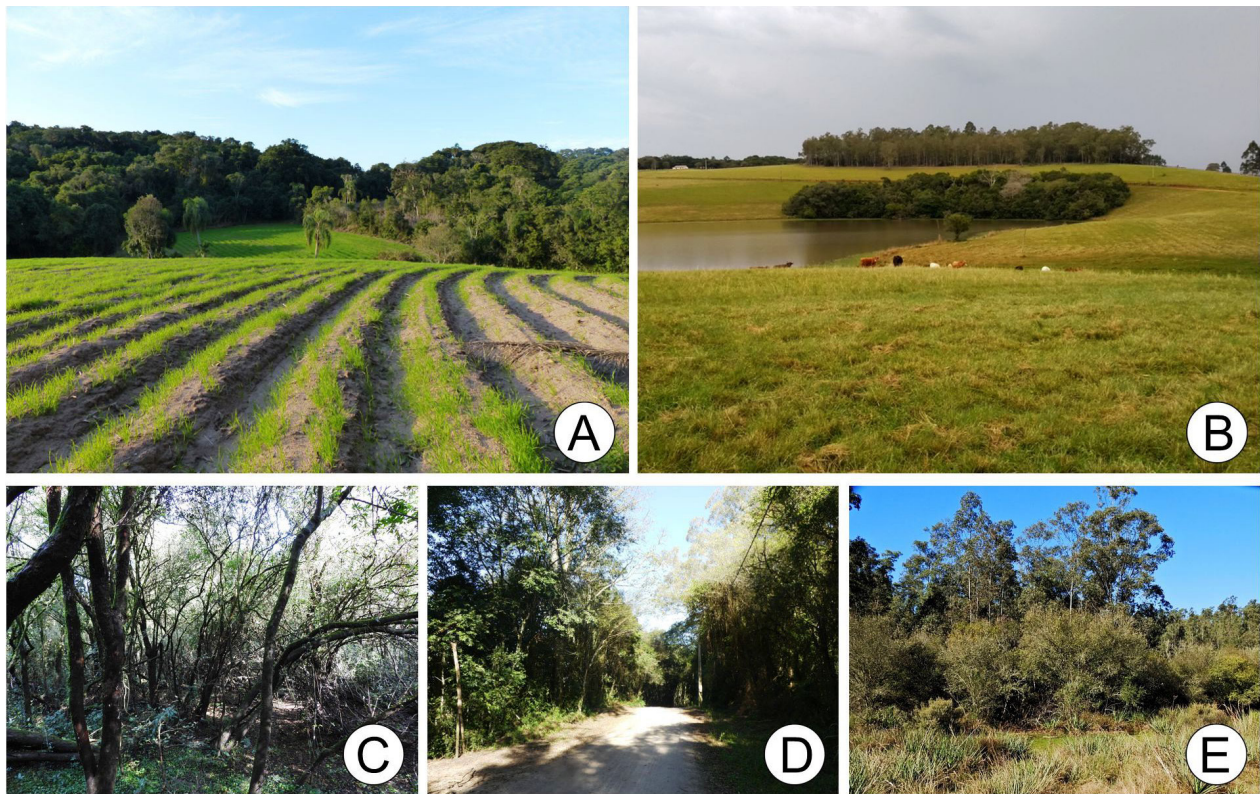

Figure 4. Landscapes of the new records localities. **A.** Semi-deciduous seasonal forests and agricultural areas in São Lourenço do Sul. **B.** Grasslands with forest fragments and *Eucalyptus* plantations in Sentinela do Sul. **C.** Riparian forest in Aceguá. **D.** Degraded semi-deciduous forest in Pelotas. **E.** Grasslands with bushes and *Eucalyptus* in Candiota. 2014), made significant contributions to our knowledge of birds in the extreme south of Brazil at the end of the 19th century (Ihering 1899), but he never deposited specimens of *T. melanops* collected in the Serra do Sudeste or mentioned this species for this region. In recently published lists of bird species in Rio Grande do Sul, *T. melanops* is only mentioned at locations north of Itapuã State Park (Accordi 2003; Accordi and Hartz 2006; Oliveira and Köhler 2010; Brummelhaus et al. 2012; Bica et al. 2014). Similarly, the online databases do not record this species south of Itapuã State Park.

In this study we discovered five new localities of occurrence of *T. melanops* in the extreme south of Rio Grande do Sul. The geographic range of *T. melanops* occurrence in Brazil is therefore expanded to the border with Uruguay with the first records of *T. melanops* for Serra do Sudeste and Campanha regions. Our Aceguá record is at the same latitude at the southern limit of the occurrence of *T. melanops* as the records of Marateo et al. (2009) for El Palmar National Park, Argentina. Relative to the previously known southern limit of distribution for the species, in the municipality of Viamão, both cases result in an approximate extension of 170 km to the south.

Marateo et al. (2009) reported two records: a female observed in June 2004 and a male observed in July 2005 and considered these records to represent vagrant. Marateo et al. (2009) suggested that these were irregular, winter occurrences for feeding and resting, with no

reproduction taking place. Their records of the species are new to the National Park and of special interest. The absence of records during the reproductive season in our study strengthens Marateo et al.'s (2009) conclusion that occurrences of *T. melanops* in these southern latitudes are seasonal displacements of scattered individuals searching for food and do not represent a colonization front with resident populations. We observed the individual from Aceguá at several times between June 3 and September 1, and it was not seen in the locality since, which suggests displacement of this individual. Our observations of this individual were mostly from beside the home of one of us (MSW), which made its monitoring easier. These non-breeding and temporary displacements of some individuals are considered short-distance and partial migrations. This kind of movement, common in Neotropical birds, is generally driven by fluctuations in food abundance (Boyle 2011) and is possibly affected by climate change (McCarty 2001). Claramunt and Cuello (2004) reported the occurrence of *T. melanops* in Uruguay (Artigas province); however, Narosky and Yzurieta (2010) and Azpiroz (2012) disregarded it from that country. This was maintained by Azpiroz et al. (2012), who excluded this species from the list of birds of Uruguay due to the lack of proper documentation.

Our record in Aceguá municipality is 12 km from the border with Uruguay, and the record at Parque El Palmar, Uruguay (Marateo et al. 2009) is only 8 km from the border with Argentina. These data suggest that the

presence of *T. melanops* in Uruguay should be better investigated, especially near the borders with Brazil and Argentina (Cerro Largo, Rivera, Artigas, Salto and Paysandu Departments).

The lack of records before 2004 at latitudes south of Viamão municipality may lead us to believe that the occurrence of *T. melanops* in extreme southern Brazil is a recent phenomenon, possibly driven by recent global climate change. However, it is possible that these seasonal displacements are now better documented and reported due to a growing number of birdwatchers and the availability of online databases, which makes it easier to report and divulge occurrence data.

Rodrigues (1995) demonstrated the flexibility of *T. melanops* in exploring different kinds of substrates, especially in the understory. Fávaro and Anjos (2005), who analysed variables in the microhabitat of *T. melanops*, suggested that this species explores diverse habitats. We found this species in riparian forests with small trees and a flora low in species richness, in predominantly grasslands, and degraded areas with a dominated by silviculture and agriculture, which suggests that *T. melanops* is able to adapt, at least in the winter, to non-forested and heavily anthropogenic habitats with fragmented vegetation.

We continue to search for *T. melanops* in all seasons at the localities reported here and also in other places in the Campanha and Serra do Sudeste regions. We encourage other birdwatchers and researchers to search as well, so that a better understanding can be made of this species' occurrence at the southernmost limit of its geographic distribution.

Acknowledgements

We thank Adolf Wall, Julianita D. Moraes, and Rudimar de Matos for providing field data and photographs of individuals and localities. We also thank Caio J. Carlos, Danielle Franco, and Robert Forsyth for the contributions to the manuscript.

Authors' Contributions

GCG, MSW, FPJ realized field records; GCG contacted collaborators; HNC produced the figures, GCG, TCF, FPJ, HNC, MSW wrote the manuscript.
