Abstract

New records of the Endangered *Catagonus wagneri* (Rusconi, 1930) are reported in Campo Grande Community of peasants, northwestern Santiago del Estero, Argentina. The new records were obtained through camera traps as well as the finding of a skull and footprints. We conducted interviews confirmed the historical presence of the species. The records indicate the presence of *C. wagneri* in the North Biological Corridor, expanding this species' distribution in Santiago del Estero province, providing initial evidence of potential connection between northern and southern populations.

Keywords

Biological corridors, distribution, Dry Chaco, endangered species, peasant territories

Introduction

Catagonus wagneri (Rusconi, 1930), commonly known as Chacoan Peccary or Quimilero in Spanish, is the largest species within Tayassuidae (Maffei et al. 2008). It was known only as a fossil by Rusconi (1930) until it was rediscovered as an extant species in 1975 (Wetzel et al. 1975). It is endemic to the Great South American Chaco ecoregion (Taber et al. 1994), and its known distribution is restricted to the driest portion of the ecoregion in western Paraguay, southeast Bolivia, and northern Argentina (Altrichter 2006; Gasparini et al. 2013; Altrichter et al. 2015; Torres et al. 2017). In Argentina, its presence has been documented from six provinces: Chaco, Córdoba, Formosa, La Rioja, Salta, and Santiago del Estero (Camino and Torres 2019). In the latter province, there is a record of a skull found in Tintina in 2016, which represented the southernmost locality until 2017 when a *C. wagneri* was confirmed in northern Córdoba, expanding the species' distribution 650 km south (Torres et al. 2017, 2019).

Catagonus wagneri is a territorial and diurnal (Mayer and Wetzel 1986; Taber et al. 1994). It lives in groups of 2–9 individuals, with an average of 4.5 individuals per group (Mayer and Wetzel 1986; Taber et al. 1994), but with lower number in areas with hunting pressures (Mayer and Brandt 1982; Taber et al. 1994; Altrichter and Boaglio 2004). Solitary Chacoan Peccaries are also commonly observed (Mayer and Brandt 1982). The diet of *C. wagneri* includes various species of cacti such as *Opuntia quimilo* K. Schum., from which the name Quimilero is derived. *Catagonus wagneri* is more abundant in areas with high cover of cacti species (Altrichter et al. 2016; Camino 2016). It also consumes roots, leaves, and fruits (Camino 2016; Altrichter et al. 2017).

Catagonus wagneri has been categorized as Endangered by the International Union for the Conservation of Nature (IUCN) (Altrichter et al. 2015) and by the local Sociedad Argentina para el Estudio de los Mamíferos (SAREM) (Camino and Torres 2019). There are serious concerns about the long-term persistence of this species, with declines mainly caused by habitat fragmentation and deforestation (Altrichter et al. 2015, 2016; Camino and Torres 2019). Unsustainable hunting is also affecting *C. wagneri* populations (Altrichter 2005, 2006; Camino and Torres 2019). The Chaco ecoregion currently presents one of the highest rates of deforestation anywhere in the world (Piquer-Rodríguez et al. 2015; Vallejos et al. 2015; Volante et al. 2016; Baumann et al. 2017). A large portion of this region has been transformed into intensive production systems for agriculture or livestock, which has highly fragmented habitats of *C. wagneri* (Periago et al. 2015; Altrichter et al. 2016; Volante et al. 2016). Furthermore, protected areas in the region are not sufficient to assure the subsistence and connection of *C. wagneri* populations (Matteucci

and Camino 2012; Vallejos et al. 2015; Periago et al. 2015; Nori et al. 2016).

In the Argentine Dry Chaco ecoregion, a large proportion of the natural ecosystems where *C. wagneri* persists is part of the territories of peasant and indigenous communities (Camino et al. 2018; Macchi et al. 2020). Peasants and indigenous people have private, communal, or informal land tenure systems (occupying public lands) and do not practice deforestation and intensive production of export products (Aguiar et al. 2018). They rely on the natural ecosystem, practicing subsistence hunting and gathering, small-scale agriculture, and extensive livestock farming (Camino et al. 2018). The creation of biological corridors in these areas could represent a support system for wildlife. As evidence of this, several species of special interest (endemic, emblematic, and endangered) have been recorded in territories of peasant and indigenous communities (Periago et al. 2015; Torres et al. 2019; Nanni et al. 2020).

We report new records of *C. wagneri* from Santiago del Estero province. The records were obtained through wildlife participatory monitoring developed in cooperation with a local association of small-scale producers, the Union de Pequeños Productores del Salado Norte (UPPSAN) (PVU - Nuestra Tierra Nuestro Monte 2018). The area where we conducted our work has been assigned to the Santiago del Estero North Biological Corridor by the government of the province of Santiago del Estero in 2015.

Methods

Our study area is located in the Dry Chaco (Fig. 1A) of northern Santiago del Estero and is inhabited by 60 peasant communities who are members of the UPPSAN association (Fig. 1B). The territory of these communities covers around 300,000 ha and are part of the Northern Biological Corridor of Santiago, which was declared by the provincial government (Government of Santiago del Estero 2015). This corridor connects the Copo National Park with the Figueroa Multiple Use Reserve wetland (Fig. 1B).

The area presents typical Dry Chaco vegetation with thorny dense shrubby cover (Oyarzabal et al. 2018). Here, three types of habitats can be differentiated: i) a high vegetation with a mixture of shrublands and medium-tall xerophilous forests dominated by *Sarcoramphus mistol* (Griseb.) Hauenschild, *Prosopis ruscifolia* Griseb., *Schinopsis lorentzii* Engl., *Aspidosperma quebracho-blanco* Schltdl., *Prosopis alba* Griseb., *Prosopis nigra* Griseb., and *Vachellia caven* (Molina) Seigler & Ebinger (Brassiolo 2005; Oyarzabal et al. 2018); ii) a lower vegetation dominated by species of *Senegalia gilliesii* (Steud.) Seigler & Ebinger and *Celtis* sp. (Cannabaceae); iii) shrublands with dominance of *Salicornia ambigua* Michx., and the presence of *Prosopis ruscifolia* Griseb., *Schinopsis lorentzii* Engl., *Aspidosperma quebracho-blanco* Schltdl., and *Bromelia hieronymi*

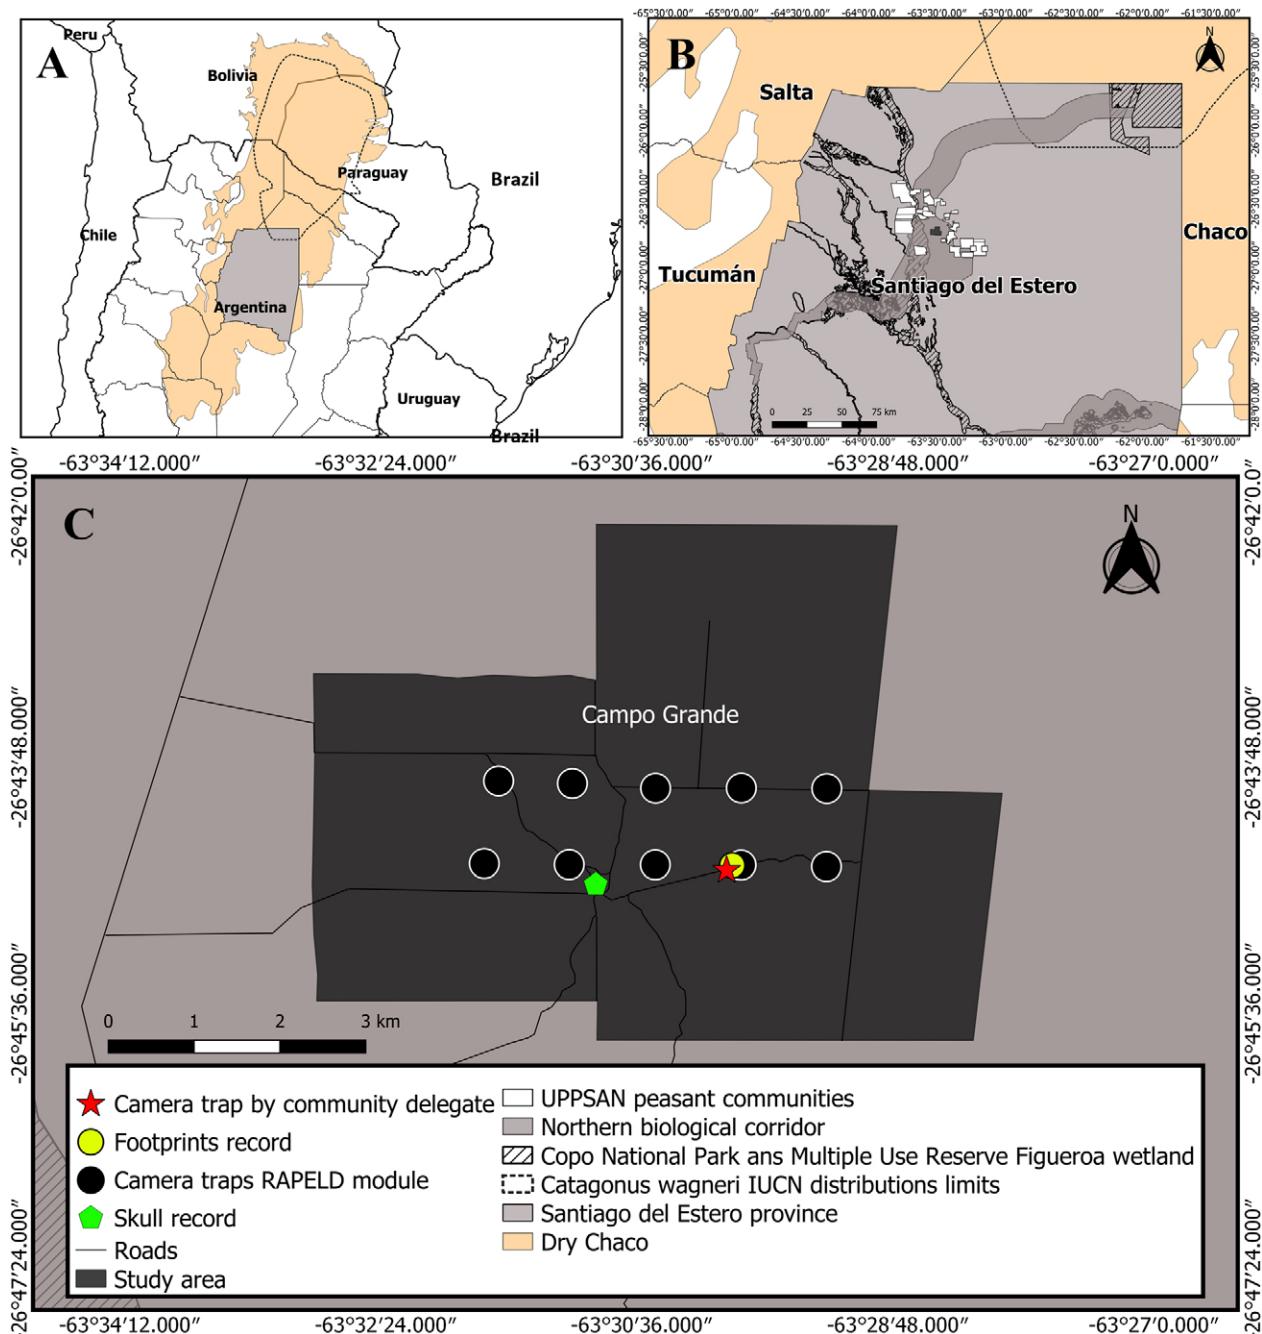

Figure 1. Study area in Santiago del Estero, Argentina. **A.** Location of the Dry Chaco, distribution polygon of *Catagonus wagneri* according to IUCN (Altrichter 2015). **B.** Portion of the map with the location of the communities that make up UPPSAN and the North Biological Corridor that runs from Copo National Park to the Figueroa Multiple Use Reserve wetland. **C.** Campo Grande community, location camera traps in the RAPELD module, location of camera trap that recorded the species (red star), location skull record and footprints record.

Mez. (Brassiolo 2005; Kunst et al. 2006; Oyarzabal et al. 2018). The three vegetation types have Cactaceae varying densities and include species such as *Opuntia qui-milo*, *Cleistocactus baumannii* (Lem.) Lem., *Harrisia pamanensis* (F.A.C. Weber ex K. Schum.), *Cereus forbesii* Otto ex C.F. Först., and *Stetsonia coryne* (Salm-Dyck) Britton & Rose (Zuloaga et al. 2019).

We follow the RAPELD methodology (RAP: rapid assessments; PELD: by Long-term Research) proposed by the Biodiversity Research Program (PPBio). PPBio proposes a collaborative work logic that allows maximizing benefits and making the most of efforts in ecological studies of biodiversity (Rossa et al. 2021). A RAPELD

module was installed in the Campo Grande community (Magnusson et al. 2005, 2013; Neme 2019) (Fig. 1C). The RAPELD methodology consists of a standardized system of transects and permanent plots (Magnusson et al. 2005). The sampling unit used was a module consisting of two 5-km long parallel trails, 1 km apart, and with 10 regularly spaced plots (Magnusson et al 2013; Paredes et al. 2017). The Campo Grande community is composed of seven peasant families who practice traditional methods of livestock grazing, small-scale agriculture, and forest-harvesting activities.

In the context of the Volunteer University Project Participatory Monitoring of Biodiversity in peasant

communities of the North Salado River (PVU - UNSE 2018), a participative inventory of wildlife was developed in cooperation with Campo Grande Community. Ten camera traps were installed in a RAPELD module for the monitoring of medium-sized and large mammals (>0.5 kg) during October and November 2018. Additional monitoring was done to search for signs and bone remains in RAPELD parcels, trails, and roads within the community's territory. We also conducted semi-structured interviews with eight members of the community, including women, men, youth, and children (<12 years), and we placed one of the camera traps at a site suggested by the community delegate (Fig. 1C).

In addition, we documented national distribution records of *C. wagneri* obtained through bibliographical research. The records were categorized according to land use by peasants and protected areas.

Results

Catagonus wagneri (Rusconi, 1930)

Figure 2

After 134 camera-days we obtained two records of *C. wagneri*. The records were obtained at the site selected by the community delegate in a zone characterized for

a dense shrubby vegetation, crossed by a livestock trail, and near a water course. We also collected the cranium of an adult *C. wagneri* hunted by a local family and we recorded footprints of this species in a transect.

New records. ARGENTINA – **Santiago del Estero province** • Alberdi department, Campo Grande community; $26^{\circ}44'35''S$, $0063^{\circ}30'00''W$; 3.XI.2018 at 13:53 h and 6.XI.2018 at 11:55 h; records by camera tramps; 1 adult, sex undetermined • same community; $26^{\circ}44'46''S$, $0063^{\circ}30'00''W$; 14.X.2018; Lucas Palomo leg; 1 skull, CBUNSE 001 • same community; $26^{\circ}44'34''S$, $0063^{\circ}29'58''W$; 11.X.2018; Andrea Neme obs; footprints.

Identification. We identified the photographed animals as *C. wagneri* (Fig. 2A, B) by their external characteristics: long dorsal pelage, light colored shoulders and semi-collar, proportionally larger head and longer ears, tail, and legs. We cannot determine if the photographs show the same or different individuals. The skull specimen lacks the lower jaw, but compared to other species of the family, it has a very well-developed rostrum and nasals that present a typical curved-vaulted shape, and a relatively small braincase. Teeth are markedly wider and larger than those of two other, smaller, sympatric species of Tayassuidae (Fig. 2C–E). The collected material has been temporarily placed in Santiago del Estero National

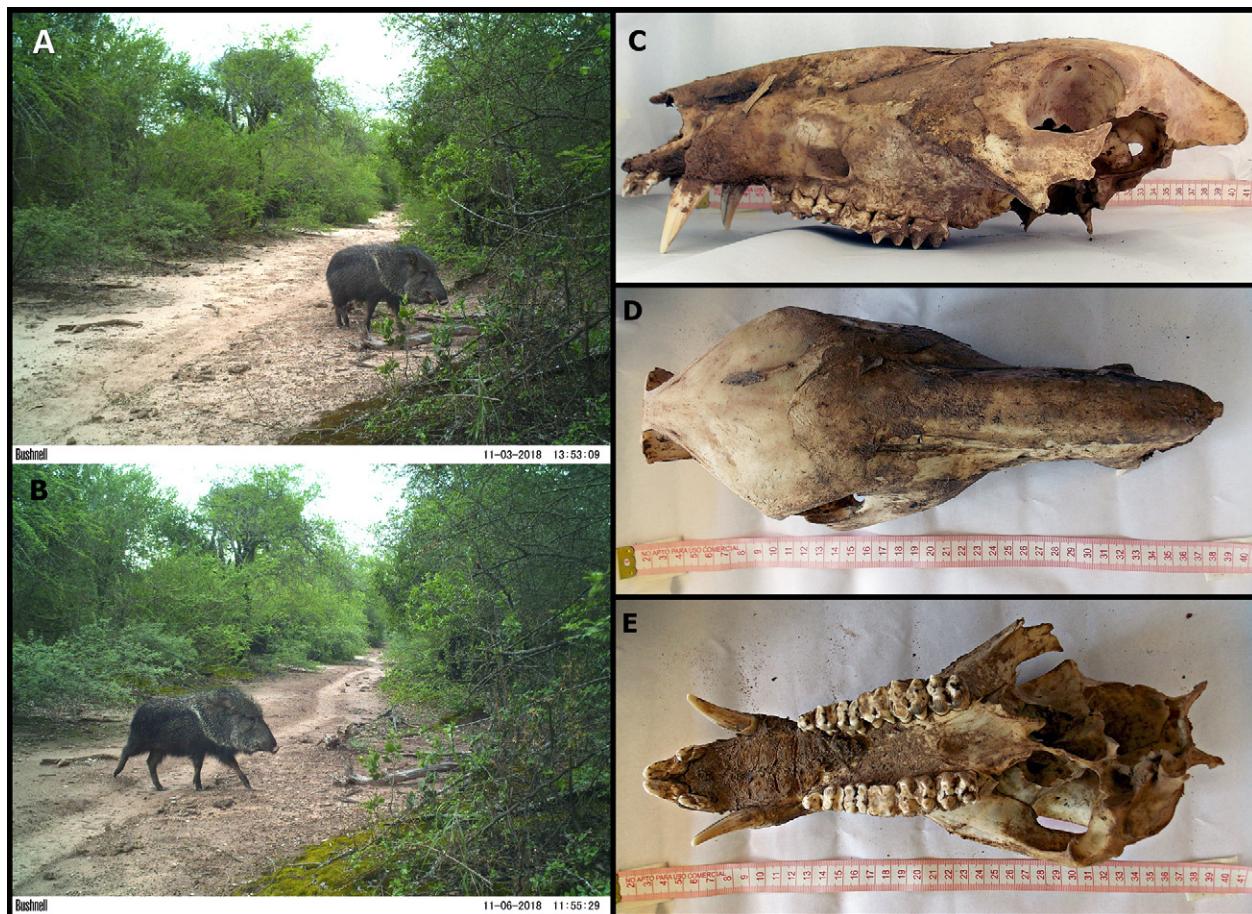

Figure 2. *Catagonus wagneri*. **A, B.** Camera trap images from the trap placed by the community delegate. **C–E.** Skull collected (CBUNSE 001): (**C**) lateral view—note the elongated nostrils, long, domed face; (**D**) dorsal view, showing the relatively small cranial case; (**E**) ventral view, showing wide and long teeth; in this specimen M2 = 18 mm and M3 = 17 mm long.

University, Facultad de Ciencias Forestales, UNSE (CBUNSE 001), and will later be deposited in the local Natural and Social Sciences Museum, in the UPPSAN peasants protected reserve. The footprints were identified according to their characteristics: two deep hoof marks with the fingers not so wide. The tips do not meet in the center.

Results of the interviews indicate that community members clearly distinguish *C. wagneri* and that this species historically inhabited the territory. They described it as a solitary or small-herd species that is larger than Collared Peccary, *Dicotyles tajacu* (Linnaeus, 1758). Also, they confirmed that *C. wagneri* is a supplementary source of protein in times of food shortage.

Based on the literature review, we found 47 localities where the species has been found to occur (Table 1); 78% of the records are in unprotected areas and 22% are in protected areas. The occurrences within the limits of the Dry Chaco ecoregion are shown in Figure 3.

Discussion

Our new records of *Catagonus wagneri* provide evidence of one population of this species in the area between the distribution according to Quiroga (2006), Altrichter et al.

(2015), and Camino (2016) and more recent records from northern Cordoba (Torres et al. 2019). Torres et al. (2019) detected the species in southern Santiago del Estero, but the presence of this species was present in northern areas of the province was unknown. We add evidence of that this species does occur in central Santiago del Estero, which supports previous studies of Camino and Torres (2019) and Torres et al. (2019).

Our study also shows the importance of the Northern Biological Corridor of Santiago as a reservoir of biodiversity and as an important corridor connecting protected areas in the Dry Chaco of Santiago del Estero (Gobierno de Santiago del Estero 2015). Protected areas, such as the Copo National Park, have higher number of records of *C. wagneri* (Fig. 3). However, the presence of this emblematic species within the biological corridor is key and proves that *C. wagneri* is using the territory. Thus, the corridor is serving its main objective.

New questions about wildlife arise from our results, especially in the context of ecosystems with extremely high land-use transformation rates (Volante 2014; Vallejos et al. 2015; Piquer-Rodríguez et al. 2015; Basualdo et al. 2019). *Catagonus wagneri* is negatively associated with human presence (Altrichter and Boaglio 2004; Altrichter 2006; Altrichter et al. 2015, 2016; Camino et al. 2020), mostly due to habitat destruction (Camino 2016), but it is likely that peasant communities can coexist with emblematic species in fragmented territories that resist large-scale transformations. Therefore, peasant production systems might be compatible with conservation along with *C. wagneri* as a food source for local peasant communities. Finally, the value of biocultural diversity (Guzmán et al. 2012; Rueda et al. 2013; Abt Giubergia 2015; Cotroneo 2017) and the connection between UPPSAN communities and their native environment is highlighted, as it has been pointed out elsewhere (Escalada 2019; Neme 2019).

Acknowledgements

We thank the University Volunteer Project (Proyecto de voluntariado Monitoreo Participativo de Biodiversidad con Comunidades Campesinas del Salado Norte. Resolución Rectoral N° 15233/2018. UNSE). We also thank the UPPSAN and the families that are part of the association, especially the Palomo family of the Campo Grande community. We acknowledge the assistance of the San Luis University Mammal Research project (PROICO-2-2818, FQBYF, UNSL) and CONICET (IMIBIO, Conicet, San Luis) for the loan of equipment and logistic aid. This work was partially financed by the Rufford Foundation. We also thank the Fauna Department and provincial Forest Administration Agency (Sub-Dirección de Fauna, Dirección General de Bosques y Fauna del Gobierno de Santiago del Estero). We thank the editor and reviewers for their valuable comments.

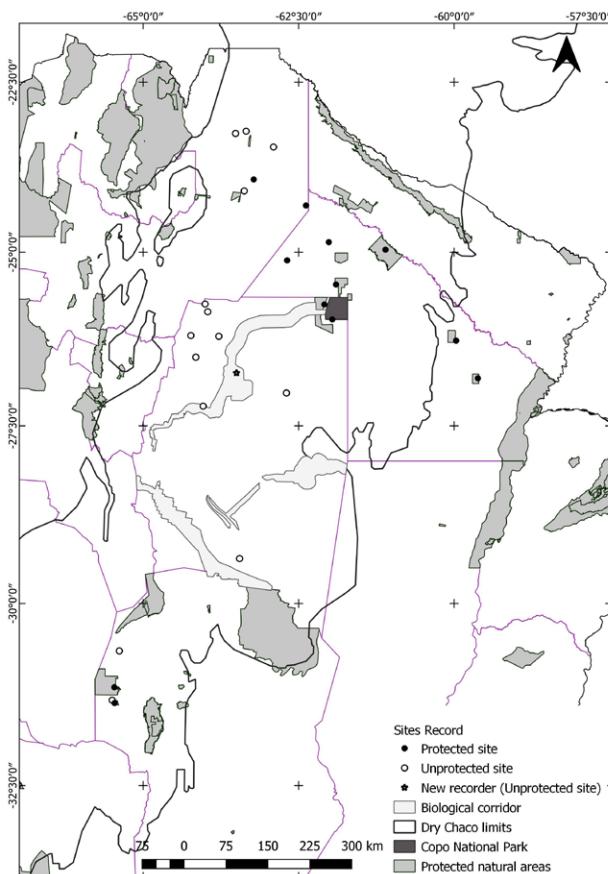

Figure 3. Distribution of records of *Catagonus wagneri* classified by category of protected area. Records in protected sites (black circle) and in unprotected sites in the Argentine Dry Chaco ecoregion. The location of the Northern Biological Corridor in Santiago del Estero province and the Copo National Park in the National System of Protected Areas (IGN 2019) are shown.
